PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5990 INFLUENCE OF THE COLONIC CONTENTS ON THE STRUCTURE AND FUNCTION OF THE RAT JEJUNAL MUCOSA. (Eng.) Menge, H.; Robinson, J. W. L.; Mirkovitch, V. (Medizinische Universitats-Klinik, Marburg-an-der-Lahn, W. Germany). *Exp. Mol. Pathol.* 26(2):204-213; 1977.

Segments of Wistar rat jejunum were transposed into the ascending colon and were examined structurally and functionally 3 weeks later to explore the influence of the colonic contents on the jejunal mucosa. For the first 3 postoperative days, the animals were nourished only with a sugared salt solution; thereafter, they received solid food *ad libitum*. The values for villus height, crypt length, villus width, epithelial cell height, and muscle thickness were 427 ± 30.1, 342 ± 13.5, 152 ± 11.5, 42.1 ± 2.4, and 235 ± 20.3 μm, resp., for the proximal region and 473 ± 18.7, 354 ± 13.1, 139 ± 9.2, 38.7 ± 1.6, and 240 ± 32.3 μm, resp., for the distal region of jejunal loops transposed into the colon. Control values were 435 ± 11.6, 185 ± 5.3, 84 ± 2.2, 28.4 ± 0.5, and 69 ± 4.6 μm, resp., for the jejunum of control rats. All of these differences between experimental and control animals were significant ($p<0.001$), except for villus height ($p>0.05$). Activities of leucine aminopeptidase, nonspecific esterase, and succinate dehydrogenase (expressed as extinction/min/μm x 10^3) were significantly lower ($p<0.001$) in the mucosae of transposed loops, being 70 ± 12, 638 ± 42, and 96 ± 10.0, resp., than control values of 341 ± 31, 1,007 ± 117, and 171 ± 9.4, resp. Sucrase activity was also significantly lower ($p<0.001$) in the mucosae of transposed loops (24.6 ± 3.6 IU/g protein) than in the jejunal mucosae of controls (47.5 ± 4.4 IU/g). Phenylalanine uptake by rings of transposed intestine was significantly ($p<0.001$) lower, being 0.211 ± 0.0344 and 0.216 ± 0.0310 μmol/100 mg fresh tissue for the proximal and distal regions, resp., than the control value of 0.519 ± 0.0123 μmol/100 mg. These results are interpreted in terms of a hyper-regenerative transformation of the mucosa of the transposed segments, induced primarily by deleterious factors present in the colonic contents.

5991 LIGHT AND ELECTRON MICROSCOPIC OBSERVATIONS OF THE AUTONOMIC INNERVATION OF THE MOUSE GALLBLADDER MUCOSA. (Eng.) Wahlin, T.; Axelsson, H.; Schiebler, T. H.; Winckler, J. (Dept. Pathology, Univ. Umea, S-901 87 Umea, Sweden). *Histochemistry* 53(2):107-116; 1977.

The autonomic nerve supply to the mucosa of the mouse gallbladder was studied by light microscopic examination of acetylcholinesterase (ACE) distribution and biogenic amine fluorescence, and by electron microscopic examination of 3% potassium permanganate-fixed tissue. Adult mice (6-7 months old, 22-28 g) were utilized. Gallbladders of 25 mice were frozen with liquid nitrogen, fixed in formalin, and incubated with 0.1 M maleate buffer (pH 6.0) containing various inhibitors, preparatory to light microscopic examination. Dense ACE reactive bundles of small nerve fascicles were noted in proximity to the basement membrane. Positive ACE activity was found in nerve-like formations perivascularly in mucosa and in the smooth muscle layer of the media. No fluorescence was exhibited by the gallbladder epithelium. In the electron microscope, fibers were seen to touch the epithelial basement membrane and, within the membrane, axonal-like varicosities with agranular vesicles were noted. No pre- or post-synaptic membrane thickenings were observed. Pilocarpine (40 mg/kg, i.p.) produced granule loss in 1.5 min, and, after continued administration at 5-min intervals for 30 min, almost complete loss of secretory granules was demonstrated. The results suggest that subepithelial connective tissue and the epithelium contain cholinergic nerves.

ABSORPTION - EXCRETION - TRANSPORT

6000 PASSIVE PERMEABILITIES OF LUMINAL AND BASOLATERAL MEMBRANES IN THE ISOLATED MUCOSAL EPITHELIUM OF GUINEA PIG SMALL INTESTINE. (Eng.) Lauterbach, F. (Institut fur Pharmakologie und Toxikologie der Ruhr-Universitat Bochum, Im Lottental, D-4630 Bochum, W. Germany). *Naunyn-Schmiedebergs Arch. Pharmacol.* 297(3):201-212; 1977.

A rapid and simple method is described for the isolation of the mucosal epithelium of guinea pig small intestine and its use in flux chambers. The isolated mucosa is almost free of additional tissues, thus permitting unhindered substrate fluxes also at the basolateral membranes of the mucosal cell. The functional integrity of the preparation was confirmed by several tests. No permeation of polyvinyl pyrrolidone (molecular weight 11,500) was detected. The permeation of polyethylene glycol (molecular weight 4000) and inulin was significantly higher in the direction blood-to-lumen than in the direction lumen-to-blood, indicating the existence of a small and asymmetric flux of these molecules across paracellular shunt pathways. Transepithelial fluxes and tissue concentrations of water and thiourea, under steady state conditions, were measured. Influx and efflux coefficients, calculated from these for a three-compartment model, were as follows in the order luminal membrane k_{in}, K_{eff}; basolateral membrane K_{in}, K_{eff}: water 1.3, 1.5, 1.2, 1.3 x 10^{-4} cm/sec; thiourea 0.6, 0.5, 0.5, 0.4 x 10^{-4} cm/sec. Coefficients for water derived from short-term influx experiments were only slightly higher. As expected for passively diffusing substrates, influx and efflux coefficients in one membrane were equal. Moreover, the passive permeabilities of the luminal and basolateral membranes were nearly identical for water as well as for thiourea. The same result was obtained for mannitol, cortisol, and phenobarbital. This property of the small intestinal mucosal epithelium may solve the problem of how to facilitate transepithelial exchange without endangering the cell of losing its essential contents, since it can be shown theoretically that the transcellular flux is maximum if a given total permeability is distributed symmetrically to two membranes in series.

6001 RELATIONS AMONG TRANSEPITHELIAL SODIUM TRANSPORT, POTASSIUM EXCHANGE, AND CELL VOLUME IN RABBIT ILEUM. (Eng.) Nellans, H. N.; Schultz, S. G. (Rochester Univ., Sch. Medicine and Dentistry, Rochester, NY 14642). *J. Gen. Physiol.* 68(4):441-463; 1976.

The relationship between transepithelial sodium transport and potassium uptake across the basolateral membranes of rabbit ileum was investigated. Potassium influx across the basolateral membranes was inhibited by the addition of 10^{-3} M ouabain to the serosal solution (0.6 ± 0.0 versus 1.7 ± 0.1 $\mu Eq/cm^2/hr$ for controls, $p<0.01$) and by the near-complete depletion of cellular sodium (0.6 ± 0.1 versus 1.3 ± 0.1 $\mu Eq/cm^2/hr$ when the serosal and mucosal sodium concentrations were 140 mM, $p<0.02$). However, potassium influx across the basolateral membranes was not affected when transepithelial sodium transport was abolished (i.e., in the presence of a sodium-free mucosal solution) or stimulated (i.e., when 10 mM D-glucose or 20 mM L-alanine was added to the mucosal solution). A relationship was not observed between the ouabain-sensitive sodium-potassium exchange mechanism responsible for the maintenance of intracellular sodium and potassium concentrations and active transcellular sodium transport. The maintenance of cell volume (water content) did not appear to be dependent on transepithelial sodium transport or on the ouabain-sensitive sodium-potassium exchange pump. Although these results cannot be considered conclusive, they raise serious questions regarding the role of the sodium-potassium exchange pump (located at the basolateral membranes) in active transepithelial sodium transport and in the maintenance of cell volume.

6002 HCO_3 TRANSPORT IN RAT JEJUNUM: RELATIONSHIP TO NaCl AND H_2O TRANSPORT IN VIVO. (Eng.) Podesta, R. B.; Mettrick, D. F. (Ramsay Wright Zoological Labs., Univ. Toronto, Toronto, Ontario M5S 1A1, Canada). *Am. J. Physiol.* 232(1): E62-E68; 1977.

HCO_3^- absorption and its association with Na^+ absorption was studied in the rat jejunum *in vivo*, using a single-pass perfusion technique. The method of disequilibrium pH was used to distinguish between an HCO_3^- pump and H^+ secretion as the mechanism of HCO_3^- absorption. HCO_3^- stimulated Na^+ absorption by 34.5 μmol/g/15 min. Na^+ deletion inhibited HCO_3^- absorption, decreased luminal acidification, and decreased the level of luminal pCO_2. These results confirm an Na^+:H^+ cation exchange. Na^+-dependent HCO_3^- absorption made up a larger part of total HCO_3^- absorption as the luminal HCO_3^- concentrations diminished, although the precise degree of Na^+-dependency could not be determined because of the unstirred layer effect. The mechanism of Na^+-independent HCO_3^- absorption was not established, but it was not affected by potential difference, Cl^-, or H_2O movements. Glucose-stimulated and HCO_3^- stimulated Na^+ absorption in the acidic postprandial jejunum is probably due entirely to the effect of free CO_2 in the lumen.

6003 EFFECTS OF CALCIUM AND MAGNESIUM IONS UPON FAT ABSORPTION BY SACS OF EVERTED HAMSTER INTESTINE.

(Eng.) Strauss, E. W. (Div. Biological and Medical Sciences, Brown Univ., Providence, RI 02912). *Gastroenterology* 73(2):421-424; 1977.

Sacs of everted hamster jejunum in bile salt solutions, with and without added calcium and magnesium salts, were studied to determine if the presence of these ions affects fat absorption in experimental systems. All solutions contained sodium taurodeoxycholate (2.4 μmol/ml), 1-[^{14}C]-linolenic or oleic acid (0.6 μmol/ml), 2-monoolein (0.3 μmol/ml), and glucose (0.3 μmol/ml). Little radioactive lipid was translocated from mucosal to serosal solution during incubations in media without added Ca^{2+} and Mg^{2+}, and triglycerides were only a small part of the total radioactive lipid. However, the tissue took up a large amount of lipid from the control medium. When 2.5 mM $CaCl_2$ or 1.2 mM $MgSO_4$ was added to the incubation medium, the sacs translocated considerable lipid into the serosal fluid, which became turbid and contained as much as 10% of the tracer that was originally present in the mucosal fluid. The intestine produced very few chylomicrons without the added ions, but at physiological concentrations of the ions, the gut preparations released numerous 0.1-μ diameter, chylomicron-like particles into the serosal fluid. The results demonstrate that incubations of everted hamster intestine in media with added Ca^{2+} and Mg^{2+} may be used in studies of intestinal triglyceride secretion.

6004 ABSORPTION OF NUTRITIONAL PROTEIN DURING AN EARLY POSTOPERATIVE PERIOD.

(Rus.) Abolimov, E. V. (S. M. Kirov Medical-Military Acad., Leningrad, USSR). *Med. Radiol. (Mosk.)* 22(9):18-23; 1977.

To examine early enteral feeding, absorption of ^{131}I-labeled albumin was studied in 128 patients undergoing surgery on the stomach and duodenum. ^{131}I-albumin was included in a standard breakfast consisting of two eggs, aminopeptide, alcohol, sugar, and sodium chloride. A specially devised coefficient of absorption rate (CAR) in the blood was assessed preoperatively and on days 1 and 2 after surgery. Postoperatively, all patients had reduced ^{131}I-albumin absorption. CAR decreased from 4.30-9.60 before surgery to 0.61-4.10 on day 1 after surgery; radioactivity of the blood reached the maximum 4 hr after isotope administration. Absorption indices showed significant improvement on day 2 after surgery; CAR ranged from 0.56 to 9.80, and the peak of blood radioactivity was reached 2 hr after isotope administration, which might be indicative of recuperation of absorption in the small intestine and improvement of the evacuatory function of the stomach.

6005 EFFECT OF DIETARY LACTOSE ON THE ABSORPTION OF SODIUM TAUROCHOLATE IN THE RAT ILEUM.

(Eng.) Riottot, M.; Sacquet, E.; Leprince, C.; Mejean, C. (Laboratoire des animaux sans Germes du C.N.R.S. au C.N.R.Z., Jouy-en-Josas, 78350, France). *Nutr. Rep. Int.* 15(4):421-427; 1977.

The absorption of radiolabeled sodium taurocholate (NaTC) in the ileum of male Fisher rats given a diet containing 10% lactose for 1 month was studied *in situ* by perfusion of an ileal loop. The intestinal pool of bile salts in rats receiving a diet with 10% lactose added before autoclaving was increased from a control value of 22.7 ± 1.2 μmol/100 g to 33.2 ± 4.1 μmol/100 g body weight ($p=0.05$). However, fecal excretion of bile salts in these lactose-fed rats (13.7 ± 0.9 μmol/100 g) was not significantly increased over the control value of 12.9 ± 0.9 μmol/100 g. When the NaTC concentration of the perfusate was increased from 5 to 25 mM, the absorption rate of NaTC in the ileum of rats receiving a diet with 10% lactose added before the diet was autoclaved increased from about 7.5 to 15+ nM/min/cm and the ileal absorption rate of NaTC in rats receiving the same diet but with 10% lactose added to the drinking water (not autoclaved) increased from about 6 to 11 nM/min/cm; control rats showed no significant change in NaTC ileal absorption rate (about 5 nM/min/cm) when the perfusate NaTC concentration was increased 5-25 mM. At a perfusate NaTC concentration of 15 mM, rats receiving lactose in their drinking water had a higher ileal NaTC absorption rate (about 11 nM/min/cm) than rats receiving a diet with lactose added before autoclaving (absorption rate, about 8 nM/min/cm). These results suggest that dietary lactose increases the intestinal pool of bile acids by increasing bile acid absorption rate and that this effect of lactose is not subordinated to a modification of bile acid synthesis.

6006 THE EFFECTS OF ENDOTOXEMIA AND FLUID EXPANSION ON GASTRIC HEMODYNAMICS AND MUCOSAL PERMEABILITY IN THE BABOON.

(Eng.) Zinner, M. J.; Gurll, N. J.; Reynolds, D. G. (Johns Hopkins

Hosp., Johns Hopkins Univ., Baltimore, MD). *J. Surg. Res.* 22(6):605-610; 1977.

The effects of the administration of sublethal i.v. endotoxin on gastric hemodynamics and mucosal ionic permeability were studied in eight adult baboons. An internally drained Heidenhain pouch was constructed in each animal 2 weeks prior to testing. Ionic fluxes were determined by instillation and recovery of an acid test solution (ATS) containing 80 mM HCl and 80 mM NaCl. Four hours of endotoxemia resulted in significant decreases in cardiac output and mucosal blood flow to about one-half of control values. There was a small but insignificant increase in hydrogen back diffusion from -58 ± 26 to -131 ± 59 μEq/30 min/100 cm^2 and no significant change in sodium flux from +183 ± 44 μEq/30 min/100 cm^2 with shock. Endotoxic shock resulted in a significant decrease in the transmucosal electrical potential difference from 40 ± 3 to 29 ± 4 mV with a significant increase in potassium flux from 6 ± 2 to 11 ± 3 μEq/30 min/100 cm^2, both indicating mucosal damage. All pouches developed acute superficial erosions. Fluid resuscitation corrected blood flow and cardiac output without significantly changing ionic fluxes or potential difference. In the baboon, endotoxemia and its attendent ischemia in the presence of acid may result in clinically significant stress ulcers without significant increases in gastric mucosal ionic permeability.

6007 INTERACTION OF BROMOSULFOPHTHALEIN WITH MITOCHONDRIAL MEMBRANES: EFFECT ON ION MOVEMENTS. (Eng.) Schwenk, M.; Burr, R.; Baur, H.; Pfaff, E. (Inst. Toxicology, Univ. Tubingen, D-7400 Tubingen, W. Germany). *Biochem. Pharmacol.* 26(9):825-832; 1977.

The interaction of BSP with mitochondrial membranes was investigated in terms of the effect of BSP on ion movements. An increase in negative surface charge density, resulting from the binding of the anionic dye BSP to mitochondrial membranes, affected the movement of a variety of ions, depending on the dye concentration. Acidification on respiration of mitochondrial suspensions was increased by very small concentrations of BSP (3 nmol/mg protein), reflecting an increased transmembranal pH gradient. The effect was mainly due to inhibition of phosphate translocation. Mitochondrial swelling experiments showed that transport of inorganic phosphate across the mitochondrial membrane was inhibited in both directions. Concentrations of BSP greater than 100 nmol/mg protein resulted in a membrane destabilization, which was reflected by a release of calcium ions and a subsequent increase in membrane permeability for succinate and inorganic phosphate. All of the effects of BSP were freely reversible by the addition of albumin, to which the dye is bound with high affinity. When the effect of BSP on phosphate transport and uncoupled respiration of mitochondria was compared with that of similar compounds (bromthymolblue, bromophenolblue, bromophenolred, phenolred, bengal rose, fluorescein, 1-anilino-naphthalene-8-sulfonic acid, sodium dodecylsulfate, taurocholate, and tetrabromophenolphthalein), BSP had by far the strongest inhibitory effect on both mitochondrial functions.

6026 THE EFFECT OF CHOLECYSTOKININ ON HUMAN TAENIA COLI. (Eng.) Egberts, E. H.; Johnson, A. G. (Charing Cross Hosp., Fulham Palace Rd., London W68RF, England). *Digestion* 15(3):217-222; 1977.

The effects of cholecystokinin (CCK), CCK-octapeptide, and glucagon on human colonic muscle were investigated. Superfusion of 12 human taenia coli strips with CCK, CCK-octapeptide, and glucagon at doses of 25-1,000 milli Ivy Dog U/ml evoked muscular contractions. Dose-dependent response to acetylcholine (ACH, 0.15-1.0 μg/ml) was not altered by an underlying contraction induced by CCK, CCK-octapeptide, or glucagon. Although atropine (0.1 μg/ml) abolished ACH effects, hormonal responses were unaffected. The muscle's sensitivity was highest to CCK and lowest to CCK-octapeptide, and the sigmoid colon was more sensitive than other parts of the bowel to both. The addition of glucagon had no effect on CCK-induced responses. The results suggest that CCK and CCK-octapeptide act directly on the taenia coli. Biologically active impurities in the whole CCK preparations explain their apparent increased activity.

SECRETION AND METABOLISM

Stomach

6037 A CHRONIC GASTROSTOMY AND TEST SYSTEM FOR EVALUATION OF GASTRIC SECRETIONS IN RHESUS MONKEYS. (Eng.) Houghton, P. W.; Jones, D. C. L. (Stanford Res. Inst., Menlo Park, CA 94025). *Gastroenterology* 73(2):252-254; 1977.

A test system was developed for the evaluation of gastric secretion in the rhesus monkey on a chronic basis that does not require the usual restraining techniques. The system is characterized by ease of animal maintenance and handling, reliability in introducing test substances into the stomach, and long-term postsurgical stability. The system comprises a surgical preparation whereby the gastrostomy tube is inserted permanently in the stomach, is passed s.c. up the back, and is exteriorized at the top of the skull, and a training procedure that conditions the monkeys so as to facilitate easy handling during the administration of test substances and the collection of gastric controls. Values for pH, volume, total acid, and acid concentration appear reasonably consistent under base-line (no test substance) conditions as well as after the intragastric administration of water or the s.c. injection of Histalog. Thus, this test system is characterized by painlessness, ease of maintenance and handling of the primates, long-term utility, and reasonable consistency of gastric secretory parameters.

6038 SERUM GASTRIN LEVELS AND GASTRIC ACID SECRETION IN INFANTS. (Ger.) Becker, M.; Fritsch, W. P.; Hausamen, T. U.; Rutthauwe, H. W. (Universitats-Kinderklinik, Adenauerallee 119, 5300 Bonn, W. Germany). *Dtsch. Med. Wochenschr.* 101(49):1800-1805; 1976.

Gastric acid secretion was measured in 20 neonates (divided into 4 groups with average ages of 8, 72, 199, and 391 days), and it was correlated with age, weight, and body surface. Secretion was measured before and after stimulation with pentagastrin (6 μg/kg, s.c.). Measurements of gastrin concentration in the serum were also made for 154 healthy adults (control group) and 10 pregnant women. Parietal cell immaturity was noted for the first 6 months of life. Measurement of fasting serum gastrin concentration by radioimmunoassay in the 20 neonates indicated an increase in the basal gastrin secretion from 0.103 mmol/hr (8 day old) to 0.322 mmol/hr (391 day old); an increase in the maximal acid secretion from 0.163 mmol/hr (8 day old) to 3.93 mmol/hr (391 day old) was noted, and a maximal gastrin secretion of 0.24 mmol/hr (8 day old) to 5.48 mmol/hr (391 day old) was observed. The average basal pH values were 4.6 (8 days), 4.0, 2.4, and 2.0 (391 days). The average pH values after pentagastrin stimulation were 3.1 (8 day old) and around 1.3-1.7 for the other three groups. The serum gastrin concentration showed an exponential decrease during the 1st yr of life. The serum concentration of the pregnant women was similar to the control group (healthy adults). Following oral feeding with breast milk, an increase in serum gastrin concentration was observed. The significantly higher serum gastrin concentrations noted in infants, as compared to the adults and pregnant women, suggested a *de novo* synthesis in the infant, as well as a negative feedback mechanism between gastric acid secretion and serum gastrin levels.

6039 SECRETORY SURFACE AREA AND PHOSPHATASE ACTIVITY OF FROG GASTRIC MUCOSA. (Eng.) Helander, H. F.; Durbin, R. P. (Dept. Anatomy, Univ. Umea, S-901 87 Umea, Sweden). *Am. J. Physiol.* 232 (1):E48-E52; 1977.

Oxyntic cell ultrastructure and enzyme changes were studied before and after the stimulation of secretion in the frog gastric mucosa. Gastric mucosae were isolated from *Rana temporaria*, after 5-7 hr, and after stimulation with histamine (10^{-4} M) and theophylline (5 mM). Acid secretion increased about fourfold, and this was accompanied by a threefold increase in secretory surface of the oxyntic cells, as determined in electron micrographs with conventional morphometric techniques. At the same time, phosphatase activity of the secretory surface increased from an unstimulated level of 49 ± 11 nmol/cm^2/hr to 90 ± 24 nmol/cm^2/hr. Other experiments showed that the latter was due to an acid phosphatase, with pH optimum near 3. It appears that the increase in surface phosphatase with stimulation can be attributed to a diminished local pH and not to the increase in surface area demonstrated in this study.

6040 GASTRIC SECRETION FROM DENERVATED POUCHES AND SERUM LEVELS AFTER MEALS OF DIFFERENT SIZES AND MEAT CONCENTRATIONS IN DOGS. (Eng.) Carpentier, Y.; Woussen-Colle, M. C.; De Graef, J. (Dept. Surgery, Free Univ. Brussels, Brussels, Belgium). *Gastroenterol. Clin. Biol.* 1(1):29-37; 1977.

An investigation was undertaken to study intact physiological responses by comparing the gastric acid output to gastrin release in dogs after meals differing in volume and protein concentration. Five mongrel dogs (11-15.5 kg) were operated to prepare a denervated Heidenhain pouch from the oxyntic area and a gastric fistula. The studies took place after a 24-hr fast and meals consisted of cooked ground liver diluted with water. Each investigation was duplicated on four dogs. The liver solution was injected through a cannula into the stomach discontinuously over 20-30 min; volumes of 10, 20, or 40 ml/kg (21 g protein/100 ml) were given. Acid response (4.98-22.19 mEq/240 min) was related to the meal volume used, while the serum gastrin peaked in 15 min with 20-ml/kg and 40-ml/kg meals (peak, 168 pg/ml and 190 pg/ml, resp.). Meals with 5.25 and 21 g protein/100 ml of fixed volume (40 ml) increased gastrin to similar extents (180 and 190 pg/ml, resp.). An increased volume (10-40 ml) without alteration in protein content increased acid (4.98-9.05 mEq/240 min) and peak gastrin response (112-180 pg/ml). A 20-ml/kg liver meal produced comparable results whether ingested or injected. Repeated injections produced a relatively constant level of gastrin after 45 min, while the amount of acid increased steadily. The poor correlation between the acid output from the pouch and the serum gastrin level indicates that hormonal stimulation other than gastrin is involved in regulating gastric secretion after feeding.

6041 INFLUENCE OF ISOPROTERENOL AND CHOLESTYRAMINE ON ACUTE GASTRIC MUCOSAL ULCEROGENESIS. (Eng.) Ritchie, W. P., Jr.; Shearburn, E. W., III. (Univ. Virginia Sch. Medicine, Charlottesville, VA 22903). *Gastroenterology* 73(1):62-65; 1977.

A recently proposed model in which bile acid-induced H^+ "back diffusion," gastric mucosal ischemia, and intraluminal acid were implicated in the pathogenesis of gastric stress ulceration was tested by selectively mitigating either the ischemic or the back diffusion components of the model. Vascularized wedges of proximal canine gastric wall mounted in Lucite chambers were studied. With the mucosa directly visualized, control group A (6 dogs) was subjected sequentially to topical acid test solution alone (ATS), ATS plus hemorrhagic shock (S), and ATS plus S plus topical 5 mM Na taurocholate (TC). Study group B (6 dogs) was subjected to ATS, ATS plus S plus isoproterenol (1.5 μg/kg/min infused into the splenic artery), and ATS plus S plus TC plus isoproterenol. Study group C (6 dogs) was subjected to ATS, ATS plus S plus cholestyramine (C, 4 g/l), and ATS plus S plus TC plus C. During each period, the net flux of H^+, the electrical potential difference, and the aminopyrine clearance (AC) were determined. Mucosal damage (intramucosal hemorrhage, erosions, and ulcers, graded 0 to 5) was assessed blindly by an independent observer using photographs. Despite H^+ back diffusion comparable to ATS plus S plus TC, intraarterial isoproterenol significantly protected against lesion formation by increasing AC. Despite a reduction in AC comparable to ATS plus S plus TC, topical C significantly protected against lesion formation by preventing excessive back diffusion of H^+.

6042 ASPIRIN ESTERASE OF GASTRIC MUCOSAL ORIGIN. (Eng.) Builder, J.; Landecker, K.; Whitecross, D.; Piper, D. W. (Royal North Shore Hosp., St. Leonards, N.S.W. 2065, Australia). *Gastroenterology* 73(1):15-18; 1977.

Aspirin esterase was found in gastric mucosal specimens obtained from surgically resected tissue; its properties and its relation to gastric disease were studied. The enzyme was stable to storage and active at two pH optima (2.5 and 8). Alcohol in the reaction mixture produced a net effect of slowing the rate of aspirin hydrolysis; this was attributable to a marked inhibitory effect on aspirin esterase activity that was not completely counteracted by the increased rate of spontaneous breakdown of aspirin by alcohol. Age, sex, or gastric disease state of the patient from whom the tissue was obtained did not significantly alter the level of enzyme activity measured, nor were different levels obtained from body or antral mucosa. In patients with gastric ulcer, those with a previous history of regular aspirin consumption did not show significantly different levels from those without such a history. It is concluded that aspirin esterase activity of gastric mucosa is not alone a significant factor in any role acetylsalicylic acid may play in the etiology and natural history of chronic peptic ulcer.

Pancreas

6059 EFFECTS OF AN ATP ANALOGUE (α,β-METHYLENE-ADENOSINE-5'-TRIPHOSPHATE) ON CYCLIC AMP AND CYCLIC GMP LEVELS, ^{45}Ca EFFLUX, AND PROTEIN SECRETION FROM RAT PANCREAS. (Eng.) Heisler, S. (Departement de Physiologie et pharmacologie, Centre Hospitalier Universitaire, Universite de Sherbrooke, Quebec, Canada). *Can. J. Physiol. Pharmacol.* 54(5): 692-697; 1976.

The effect of α,β-methylene-adenosine-5'-triphosphate (Ap[CH$_2$]pp), an ATP analog and competitive inhibitor of adenylate cyclase, upon ^{45}Ca efflux, nucleotide levels, and protein secretion from rat pancreas was studied *in vitro* to establish the relationship between its two functions. Incubation of rat pancreatic fragments with 2.5 and 5.0 mM Ap(CH$_2$)pp for 3 and 5 min did not affect basal cyclic AMP (cAMP) levels. Carbachol (0.01 mM)-stimulated ^{45}Ca efflux, and basal ^{45}Ca efflux were also not affected by 1.0, 2.5, or 5.0 mM Ap(CH$_2$)pp after a 20-min incubation. Ap(CH$_2$)pp (1.0, 2.5, and 5.0 mM) did not significantly affect the synthesis of cyclic 3',5'-guanosine monophosphate (cGMP) in response to carbachol (0.01 mM), pancreozymin (PZ, 1.0 Crick U/ml), or calcium ionophore (A-23187, 2 μg/ml) stimulation. However, a 1-hr incubation with 5 mM Ap(CH$_2$)pp increased ^{3}H-zymogen protein secretion from 3.93 ± 0.19% to 5.89 ± 0.26% of the total trichloroacetic acid-insoluble protein in the medium, reduced carbachol (0.01 mM)-stimulated zymogen secretion from 10.09 ± 0.43% to 7.70 ± 0.20%, and increased dibutyryl cAMP (1.0 mM)-stimulated zymogen secretion from 6.93 ± 0.17% to 9.04 ± 0.72%. Although dibutyryl cAMP potentiated carbachol-stimulated protein secretion, Ap(CH$_2$)pp (5 mM) reduced the dibutyryl cAMP + carbachol response from 35.61 ± 1.90% to 18.37 ± 0.85%. Ap(CH$_2$)pp (5 mM) also inhibited the zymogen secretion stimulated by PZ (1.0 Crick U/ml) and A-23187 (5 μg/ml). It is concluded that Ap(CH$_2$)pp acts at a specific step in the secretory response since it inhibited the action of all the secretagogues except dibutyryl cAMP. Since Ca^{2+} efflux, cGMP synthesis, and protein secretion precede the effect of Ap(CH$_2$)pp, Ap(CH$_2$)pp may affect Ca^{2+} homeostasis at a point following the initial stimulus producing secretion.

6060 INHIBITION OF SECRETIN RELEASE AND PANCREATIC BICARBONATE SECRETION BY SOMATOSTATIN INFUSION IN MAN. (Eng.) Hanssen, L. E.; Hanssen, K. F.; Myren, J. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 12(4):391-394; 1977.

Studies were carried out in five healthy subjects to determine the effect of somatostatin on the release of endogenous secretin after duodenal acidification and whether the exocrine secretion of fluid and bicarbonate from the pancreas is affected. The subjects were investigated on two different days with or without a constant i.v. infusion of somatostatin (500 μg/hr). A fluoroscopically placed Lagerlof tube was used for the collection of gastric and duodenal juice. After 30-min basal period, 40 ml of 100 mM HCl was infused into the mid-duodenum over 5 min through a thin catheter attached to the tube. Plasma immunoreactive secretin was measured by radioimmunoassay employing ^{125}I-labeled synthetic secretin, antibody against synthetic secretin, and standards prepared from pure natural porcine secretin. The mean secretin level without somatostatin infusion was 4.6 ± 0.7 pM basally and rose to a peak of 21.8 ± 6.2 pM after duodenal acidification ($p<0.05$). With somatostatin infusion, the level was 4.4 ± 0.4 pM basally and rose to a peak of 6.7 ± 1.7 pM (not significant) after duodenal acidification. Pancreatic bicarbonate output increased from 8.0 ± 2.5 μmol/min to 283 ± 44 μmol/min without somatostatin infusion ($p<0.05$) and from 6.7 ± 2.1 μmol/min to 70 ± 13 μmol/min with somatostatin ($p<0.05$). This study shows that somatostatin inhibits the release of secretin and the pancreatic bicarbonate secretion after duodenal acidification in man.

6061 HORMONE STIMULATED PANCREATICO-BILIARY SECRETIONS--DO THEY PREVENT INTESTINAL MUCOSAL ATROPHY DURING INTRAVENOUS FEEDING [Abstract]. (Eng.) Hughes, C. A.; Sabin, E.; Dowling, R. H. (Guy's Hosp. Medical Sch., London SE1 9RT, England). *Arch. Dis. Child.* 52(5):428; 1977.

SECRETION AND METABOLISM

Hepatobiliary Tract

6068 AFFINITY CHROMATOGRAPHY SYSTEMS FOR ARTIFICIAL LIVER SUPPORT. (Eng.) Hughes, R. D.; Dunlop, E. H.; Davis, M.; Silk, D. B. A.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5, England). *Biomater. Med. Devices Artif. Organs* 5(2):205-221; 1977.

Two albumin-conjugated agarose materials were tested *in vitro* to determine whether they could be used in artificial liver support systems to enhance the removal of toxic protein-bound substances in cases of fulminant hepatic failure. The agarose gels tested were Bio Gel A-5M (bead size, 74-149 μm) and cyanogen bromide-activated Sepharose 6MB (bead size, 200-300 μm). The amount of albumin bound to the Bio Gel agarose beads was 46 mg/g wet agarose, compared with 71 mg/g for the Sepharose gel. The mean fractional water content of the Bio Gel albumin agarose in three experiments was 0.949 ± 0.002 versus 0.857 ± 0.070 for Sepharose albumin agarose. The mean values for the amounts of bilirubin and chenodeoxycholic acid bound to Bio Gel were 262 ± 6 and 136 ± 3 μmol/kg wet agarose, resp., compared with values of 499 ± 27 and 407 ± 9 μmol/kg, resp., for Sepharose. In terms of column hemodynamics, large pressure drops (greater than 300 mm Hg) were observed during flow experiments with Bio Gel where blood or saline was pumped over columns of albumin-agarose. Falls in pressure across the column were less with the Sepharose albumin agarose; however, even with this gel, pressures of more than 100 mm Hg were measured at flow rates of more than 20 ml/min. Although the above tests suggest that there might be advantages in using the Sepharose rather than Bio Gel albumin agarose in future hemoperfusion systems, further modifications, especially relating to improved flow properties, are needed before the former agarose material can be successfully scaled up for human use.

6069 THE AMINO ACID COMPOSITION OF RAT BILE. (Eng.) Folsch, U. R.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee DD2 1UB, Scotland). *Experientia* 33(8):1055-1056; 1977.

The amino acid composition of bile was studied in male Wistar rats and compared with amino acid levels in the serum. The bile of fasted rats contained significantly greater amounts of aspartic acid (0.770 mM) and glutamic acid (1.356 mM) than did the serum (0 and 0.147 mM, resp., $p<0.002$); the bile of fed rats also contained significantly greater amounts of these amino acids (>2.500 and 2.049 mM, resp.) than did the serum (0.261 and 0.197 mM, resp.; $p<0.002$). In contrast, the serum contained more lysine (0.237 in fasted, 0.381 mM in fed) and ornithine (0.134 in fasted, 0.261 mM in fed) than did the bile (lysine, 0.089 in fasted and 0.103 mM in fed; ornithine, 0.066 in fasted and 0.067 in fed, $p<0.001$). While bile contained appreciable amounts of cystine and methionine, cystine was absent from the serum, and only traces of methionine were detected ($p<0.001$). There were significantly greater amounts of glycine in bile compared with serum ($p<0.001$). The results indicate that bile contains significantly greater amounts of acidic and sulfur-containing amino acids and glycine than does serum, while serum contains more basic amino acids than does bile; the results indicate that the secretion of amino acids into bile may involve specific transport processes.

6070 BINDING PROPERTIES IN VITRO OF ANTACIDS FOR CONJUGATED BILE ACIDS. (Eng.) Clain, J. E.; Malagelada, J. R.; Chadwick, V. S.; Hofmann, A. F. (Groote Schuur Hosp., 7925 Cape Town, South Africa). *Gastroenterology* 73(3):556-559; 1977.

The binding properties of various commercial antacids for pure conjugated bile acids in an aqueous solution or the bile acids present in human gallbladder bile were characterized *in vitro*. Aluminum hydroxide was a potent binding agent, similar in affinity and capacity to cholestyramine. With aluminum hydroxide, dihydroxy bile acid conjugates were bound more strongly than trihydroxy bile acid conjugates, and glycine conjugates were bound more strongly than taurine conjugates; pH had no effect *per se* on binding. Magnesium hydroxide and aluminum phosphate bound bile acids much more weakly. The finding that aluminum hydroxide is superior to other antacids in binding bile acids, together with its antacid effect, suggests that it may be useful in the therapy of reflux gastritis or gastric ulcer.

6071 LONG TERM BILE COLLECTION IN THE RAT. (Eng.) Enderlin, F. E.; Honohan, T. (The Upjohn Co., Kalamazoo, MI 49001). *Lab. Anim. Sci.* 27(4):490-493; 1977.

A method for continuous bile collection from the rat over extended periods is described. Bile is collected continuously, using an externalized cannula brought through an intrascapular incision. The cannula is protected by a 30-cm, 16-gauge stainless steel tube attached to the skin through the incision. The rat is housed in a 10.2 x 10.2 x 12.7 cm cage at a level higher than the collection vial to aid in drainage of bile. A hole in the vial cap permits the cannula to turn freely as the rat moves about the cage. This method allows bile to be collected conveniently over long periods of time with minimal restraint of the animal.

6072 BILIARY COPPER EXCRETION IN MAN AND THE RAT. (Eng.) Frommer, D. J. (St. Vincent's Hosp., Sydney N.S.W. 2010, Australia). *Digestion* 15(5):390-396; 1977.

The form in which copper is bound in bile was studied in bile from patients with Wilson's disease (hepatolenticular degeneration), control subjects (normal individuals and patients with nonhepatic disease or primary biliary cirrhosis), and Sprague-Dawley rats. Bile was labeled with ^{64}Cu. Sephadex column chromatography using gels G-200 to G-10 showed a major ^{64}Cu and protein peak of between 4,000 and 5,000 daltons and a minor peak of about 8,000 daltons. A high-molecular weight peak (above 800,000 daltons), which was present when the eluting solution consisted of water or saline, was shown to be an artifact that could be abolished by the addition of bile salt (glycocholate) to the eluting solution. Bile from control subjects, Wilson's disease patients, and rats behaved in the same manner, binding Cu to low-molecular weight proteins. No evidence was found to suggest that the diminished biliary Cu excretion found in Wilson's disease can be attributed to abnormalities in the form in which Cu is present in the bile. Therefore, the inability of the liver to excrete Cu into bile in Wilson's disease must be due to an abnormality of the handling of Cu within the hepatocyte.

6073 AGE-RELATED VARIATIONS IN HEPATIC REGENERATION AND ERYTHROPOIETIN PRODUCTION IN THE RAT.

(Eng.) Naughton, B. A.; Piliero, J. A.; Kruger, R. E.; Birnbach, D. J.; Roy, M.; Piliero, S. J.; Gordon, A. S. (A. S. Gordon, Lab. Experimental Hematology, Dept. Biology, New York Univ., New York, NY). *Am. J. Anat.* 149(3):431-438; 1977.

Hepatic regenerative capacity and erythropoietin (EP) production were studied in adolescent and adult Long-Evans male rats undergoing single or repeated partial hepatectomies. The EP levels in posthepatectomized (30-72 hr), anephric, hypoxic, adolescent rats exceeded sham operated, anephric, hypoxic controls by 198%, with a peak in the EP levels occurring 72 hr posthepatectomy when most of the original liver mass had been restored. In adult rats, EP levels were significantly higher (91%) at 50-120 hr after hepatectomy in rats subsequently subjected to nephrectomy and exposed to hypoxia than in similarly treated sham-hepatectomized, anephric, hypoxic controls. The EP response to hypoxia was significantly greater in adolescent than in adult anephric rats with normal or regenerating livers. An 80-90% hepatectomy evoked an EP response that was 38% higher than in 30- to 40%-hepatectomized rats examined 72 hr after hepatectomy, subsequent nephrectomy, and exposure to hypoxia. At 72 hr after the third of three successive hepatectomies, EP levels (mean, 0.257 ± 0.013 IU) in rats weighing 300-360 g were lower than in singly hepatectomized, anephric, hypoxic rats (mean, 0.346 ± 0.008 IU) of similar age, but were significantly higher than those observed in sham-operated controls (mean, 0.215 ± 0.019 IU) and in rats subjected to four successive hepatectomies (mean, 0.198 ± 0.036 IU). Overall, the regenerative and hematopoietic potential of the liver decreased with animal age, and EP production was related to the return of liver mass to normal levels following hepatectomy in both adolescent and adult anephric, hypoxic rats.

6074 EFFECTS OF BILIARY DIVERSION ON INTESTINAL MICROFLORA IN THE RAT.

(Eng.) Burke, V.; Stone, D. E.; Beaman, J.; Gracey, M. (Princess Margaret Children's Medical Res. Foundation, Perth, Western Australia). *J. Med. Microbiol.* 10(2):241-244; 1977.

Since certain bile acids inhibit the *in vitro* growth of intestinal anaerobic bacteria, changes in intestinal flora in the rat were examined *in vivo* after diversion of bile to the urinary bladder. Five days after operation there was an increase in numbers of *Proteus* sp. in the stomach, mid-jejunum, and cecum and of coliform bacilli in the stomach and mid-jejunum, in comparison with controls. Lactobacilli were increased in the stomach. There was no change in numbers of anaerobic organisms. Similar changes in bacterial flora followed 5 days of pair feeding in control rats. These results do not suggest a specific antibacterial effect of bile salts in the rat *in vivo*. The changes found are probably related to semistarvation, because the food intake of the rats after operation was about half that of control rats having an unrestricted diet.

6075 CHANGES AFTER MAJOR RESECTION OF EXPERIMENTAL CIRRHOTIC LIVER.

(Eng.) Kohno, A.; Mizumoto, R.; Honjo, I. (Murakami Memorial Hosp., Gifu Coll. Dentistry, 6, 1-Chome, Wakamiya-cho, Gifu City, Japan, 500). *Am. J. Surg.* 134(2):248-252; 1977.

Changes after major resection of experimentally induced cirrhotic livers in dogs were investigated. Liver cirrhosis was induced either hemodynamically (constriction of the hepatic vein) or pharmacologically (dimethylnitrosamine administration), and approximately 45% of the liver was resected. The results were similar in the two experiments. Dogs with experimental liver cirrhosis did not tolerate 45% resection of the liver, with resectability being limited to 40% or less of the liver. Dogs with advanced cirrhosis died of hemorrhage and hepatic insufficiency immediately after hemihepatectomy. When the liver showed moderate cirrhosis, dogs tolerated hemihepatectomy and survived during the early postoperative period; however, they died of hepatic insufficiency within 40 days after resection, with progression of cirrhotic changes in the remnant liver. When the liver had mild fibrosis, the animals tolerated hemihepatectomy well and survived for periods ranging from 51 to 168 days before they were sacrificed. Levels of SGOT and SGPT increased immediately (more than sixfold) after hemihepatectomy and decreased rapidly to the preoperative level within 2 weeks. However, SGPT levels remained higher than SGOT levels throughout the postoperative period in all dogs. Serum albumin decreased progressively in dogs dying early, but decreased only slightly and transiently in long-term survivors after liver resection. These results indicate that death after major resection of a cirrhotic liver was caused not only by too extensive a resection, but also by the rapid progression of cirrhotic changes in the remnant liver during the postoperative course.

6076 EXPERIMENTAL CRYOPROBE PRODUCTION OF INTRAHEPATIC PORTOCAVAL SHUNT.

(Eng.) Reich, M.; Olumide, F.; Jorgensen, E.; Eiseman, B. (Univ. Colorado Sch. Medicine, West 8th Ave. and Cherokee St., Denver, CO 80204). *J. Surg. Res.* 23 (1):14-18; 1977.

The technical feasibility of using a cryoprobe to produce an intrahepatic portacaval shunt was investigated in 25 anesthetized adult pigs. The technique involved the passage of a small caliber (5 mm) cryoprobe via an incision in the portal vein to a major branch of the left hepatic vein. Directed toward a finger on the middle hepatic vein, a 9-mm diameter tunnel through 3 cm of liver tissue to the hepatic venous outflow tract was created with the cryoprobe, which was activated to a tip temperature of -90 F. The entire procedure from insertion to removal of the probe was accomplished in 2-10 min. Patent shunts were observed in 6 of 11 animals sacrificed between 5 and 56 days postoperatively; these animals, which were unheparinized, had normal portal pressures. No arteriovenous shunts were observed along the cold probe tract; apparently the cryoprobe coagulated the arterioles along the shunt. The above technique is designed ultimately to provide a relatively atraumatic method for creating an emergency portacaval shunt in patients with bleeding esophageal varices.

6077 A POSSIBLE PROTECTIVE ROLE FOR SULPHYDRYL COMPOUNDS IN ACUTE ALCOHOLIC LIVER INJURY. (Eng.) Macdonald, C. M.; Dow, J.; Moore, M. R. (Hazleton Lab. Europe Ltd., Glasgow, G.21, Scotland). *Biochem. Pharmacol.* 26(16):1529-1531; 1977.

The role of various sulfhydryl compounds in protective mechanisms against acute ethanol toxicity was investigated in the mouse. The i.p. administration of ethanol (0-6 g/kg as 20% weight/volume solutions in saline) produced a linear dose response reduction in hepatic reduced glutathione (GSH) levels. The time scale of this effect suggests that GSH depletion occurs as a consequence of hepatic damage rather than contributing towards it. β-Mercaptoethylamine-HCl, cysteine, and methionine significantly increased the survival rate of mice given a lethal dose of ethanol.

6078 STUDIES ON THE METABOLIC EFFECTS OF LONG-TERM ADMINISTRATION OF ETHANOL AND 4-METHYLPYRAZOLE IN THE RAT. VITAMIN A DEPLETION IN THE LIVER. (Eng.) Blomstrand, R.; Lof, A.; Ostling, H. (Huddinge Univ. Hosp., Huddinge, Sweden). *Nutr. Metab.* 21(Suppl. 1):148-151; 1977.

The effects of ethanol and 4-methylpyrazole on liver lipid accumulation and vitamin A concentration were studied in male Sprague-Dawley rats. The rats received 1.3 mM 4-methylpyrazole, 1.7 M ethanol, or a combination of 4-methylpyrazole and ethanol in the drinking water for 12 weeks; controls received pure water. In the rats receiving ethanol alone, the serum ethanol concentrations at 6, 8, 9, 10, and 12 weeks were 1.3, 3.3, 7.0, 8.4, and 10.4 mM, resp. In the rats receiving ethanol and 4-methylpyrazole, the respective ethanol concentrations were 13.8, 16.7, 15.8, 19.0, and 19.6 mM. The 4-methylpyrazole concentrations during weeks 6, 8, 9, 11, and 12 in the rats treated with 4-methylpyrazole alone were 0, 0, 0, 6, and 3 μM, resp., while the 4-methylpyrazole concentrations in the rats treated with ethanol and 4-methylpyrazole were 31, 8, 13, 27, and 37 μM, resp. These results indicate that 4-methylpyrazole partially inhibits the oxidation of ethanol and that ethanol interacts with 4-methylpyrazole metabolism. There was a significant accumulation of liver triglycerides both in the ethanol and in the ethanol and 4-methylpyrazole group. The partial inhibition of ethanol oxidation by 4-methylpyrazole cannot prevent liver triglyceride accumulation in chronic experiments, which indicates that ethanol *per se* might have an effect on the liver cell metabolism. The rats receiving ethanol or ethanol and 4-methylpyrazole had a hepatic vitamin A concentration less than half that of the controls.

6079 EFFECT OF ETHANOL ON URIC ACID PRODUCTION OF HUMAN LIVER. (Eng.) Grunst, J.; Dietze, G.; Wicklmayr, M. (Medizinische Klinik II, Klinikum Grosshadern, Marchioninistrasse 15, D-8 Munchen 70, W. Germany). *Nutr. Metab.* 21(Suppl. 1): 138-141; 1977.

Hepatic uric acid production was studied in six healthy subjects during the infusion of ethanol (15 g in 5 min; 0.2 g/min, 1 hr) following a 15-hr fast. During the infusion, the uric acid concentrations in the liver vein increased and reached a peak after 30 min. The uric acid level in the arterial blood did not change. Before the infusion, the measured blood flow was 80 ml/100 g liver/min; after infusion, it increased to a meal level of 93 ml/100 g/min and returned to the initial value after 1 hr. The uric acid production, calculated from arteriovenous concentration differences and liver blood flow, increased from 3.3 nmol/g liver/min in the control period to 25.7 nmol/g liver/min at the end of ethanol infusion. During the whole infusion period, the calculated uric acid output of the liver was approximately 300 mg. This study suggests that ethanol may induce the *de novo* synthesis of purine nucleotides or that there is a decrease in ATP content in the liver cell.

6080 HEPATIC DRUG ACETYLATION AND OXIDATION: EFFECTS OF AGING IN MAN. (Eng.) Farah, F.; Taylor, W.; Rawlins, M. D.; James, O. (Dept. Pharmacological Sciences, Univ. Newcastle upon Tyne, Newcastle NE1 7RU, England). *Br. Med. J.* 2(6080): 155-156; 1977.

The half-lives of acetanilide and isoniazid ("model" substrates for oxidation and acetylation, resp.) were determined in groups of young (aged 20-35 yr) and elderly (aged >65 yr) people. Isoniazid half-lives were distributed similarly in both populations, whereas acetanilide half-lives were significantly longer in the elderly (2.07 hr versus 1.45 hr). The results suggest that liver function does not deteriorate uniformly with age and that heterozygotes for acetylation do not possess survival advantages during their middle-age years.

6081 PRODUCTION OF α-FETOPROTEIN BY CULTURED RAT ASCITES HEPATOMA CELLS DETERMINED IN VIVO AS α-FETOPROTEIN-NEGATIVE. (Eng.) Isaka, H.; Koura, M.; Koura, S.; Yoshii, H.; Hattanmaru, M.; Tsukada, Y.; *et al.* (Kagoshima Univ. Sch. Medicine, 1208-1 Usuki-cho, Kagoshima 890, Japan). *Gann* 68(3):363-367; 1977.

Three rat ascites hepatoma cell lines, AH-41B, AH-34, and AH-64B, which had been determined *in vivo* as α-fetoprotein-negative, were cultured *in vitro* in media containing cyclic AMP (0.5-2.0 mM), cyclic dibutyryl-AMP (0.1-1.0 mM), or theophylline (0.1-

1.0 mM). The concentration of α-fetoprotein in the culture media was measured by ^{125}I-radioimmunoassay. In comparison with untreated control culture media, the α-fetoprotein concentrations of the AH-41B cells in cultures containing cyclic AMP, cyclic dibutyryl-AMP, and theophylline were increased; the levels in the respective cultures were $1.0\text{-}1.3 \times 10^{-5}$, $1.1\text{-}1.3 \times 10^{-5}$, and $0.7\text{-}1.0 \times 10^{-5}$ ng/cell, in comparison with 0.7×10^{-5} ng/cell in the control cultures. The effects of cyclic AMP, cyclic dibutyryl-AMP, and theophylline were not seen in the other two cell lines.

6082 FATTY LIVER INDUCED IN ZUCKER "FATTY" (ff) RATS BY A SEMISYNTHETIC DIET RICH IN SUCROSE. (Eng.) Novikoff, P. M. (Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, NY 10461). *Proc. Natl. Acad. Sci. USA* 74(7):3038-3042; 1977.

The use of a sucrose-enriched semisynthetic diet for the production of fatty liver in 2- to 4-month-old homozygous mutant Zucker fatty (*ff*) rats is described. The rats were fed for 1 or 3 weeks on the experimental diet, which consisted of 60% sucrose, 20% vitamin-free casein, 4% corn oil, 1% vitamin mixture, 4% salt mixture, and 10% cellulose. The *ff* rats fed the experimental diet developed a marked fatty liver after 1 week of feeding, whereas lean littermates fed the experimental diet did not. The increased liver size in *ff* rats on the experimental diet was due to the enlargement of individual hepatocytes, as they accumulated large lipid spheres throughout the cytoplasm. On standard rat chow, 7-month-old *ff* rats showed no such lipid accumulation; these animals showed only a mild increase in the number of small sinusoidal lipid droplets, compared with the younger *ff* rats.

6083 ACCUMULATION OF NASCENT LIPOPROTEINS IN RAT HEPATIC GOLGI DURING INDUCTION OF FATTY LIVER BY OROTIC ACID. (Eng.) Sabesin, S. M.; Frase, S.; Ragland, J. B. (Center for the Health Sciences, Univ. Tennessee, 951 Court Ave., Room 335M, Memphis, TN 38163). *Lab. Invest.* 37(2):127-135; 1977.

The ultrastructure of fatty liver induced by 1% orotic acid (OA) in the diet was studied in an attempt to correlate the resulting hepatic secretory defect in very low density lipoproteins (VLDL) with specific alterations in the organization of hepatocyte subcellular organelles. Inasmuch as the final assembly of VLDL occurs in the Golgi apparatus and lipoprotein secretion is mediated by the release of VLDL from Golgi-derived secretory vesicles, studies were carried out to determine whether OA prevents the nascent VLDL from entering the Golgi. Groups of female rats were sacrificed at 6 and 12 hr after OA feeding and at daily intervals thereafter until 8 days. There was a rapid depression of plasma triglycerides after OA feeding and a progressive increase in hepatic triglyceride content. Ultrastructural studies demonstrated an accumulation of VLDL-size droplets in hepatic Golgi as early as 24 hr after OA feeding. By 72 hr, a remarkable alteration in the organization of the hepatocyte smooth and rough endoplasmic reticulum (ER) was apparent, resulting in distention and vesiculation of ER cisternae due to an accumulation of lipid droplets. Small lipid droplets within the ER coalesced to form large osmiophilic droplets that eventually formed membrane-bound vesicles or liposomes. Although the accumulation of lipid within the vesiculated elements of the ER was progressive, VLDL-size droplets were always visualized within elements of the Golgi apparatus. Studies performed from 72 hr to 8 days after OA feeding revealed a progressive accumulation of fat within distended and vesiculated channels of the ER; however, VLDL-like particles were readily visualized within the Golgi. In Golgi fractions that were purified from rat liver homogenates on discontinuous sucrose density gradients and negatively stained for electron microscopy, VLDL-like droplets accumulated with Golgi elements even after 8 days of OA feeding. These observations indicate that the development of fatty liver in rats fed OA is associated with an accumulation of nascent VLDL in hepatocyte Golgi. Since OA produces a selective defect in VLDL secretion it appears that the biochemical effect of OA occurs at the level of the Golgi apparatus and may be related to an impairment of the final steps in VLDL biosynthesis.

6084 EFFECTS OF LITHOGENIC DIETS ON MOUSE GALLBLADDER EPITHELIUM: A HISTOCHEMICAL, CYTOCHEMICAL, AND MORPHOMETRIC STUDY. (Eng.) Wahlin, T. (Dept. Histology, Univ. Umea, S-901 87 Umea, Sweden). *Virchows Arch.* [*Cell Pathol.*] 22(4):273-286; 1976.

To study the process of gallstone formation, particularly the structural and histochemical alterations in the gallbladder epithelium, lithogenic diets were fed to 90 adult C57BL black mice of both sexes. Groups of 30 mice each were fed diets of either 1% cholesterol plus 0.5% cholic acid (diet NCC), a glucose-rich fat-free composition (diet 284), or normal chow (control diet). Ten mice from each group were sacrificed 2, 4, and 8 weeks after beginning these diets and their gallbladders were examined by light and electron microscopy. Diet 284 produced no obvious alterations in gallbladder morphology as compared to controls, nor was size or bile content increased, and no gallstones were found. After 2 weeks of the NCC diet, however, gallbladders were noticeably distended and hyperplasia of the mucosa produced a thickening of the gallbladder walls. An increase in glycoproteins was demonstrated histochemically (PAS and Alcian blue at pH 2.5) in cells near the bottom of the crypts and in the mucosal folds; there were ultrastructural changes in the principal cells of this region, including numerous supranuclear Golgi complexes with many vesicles and distended saccules and other evidence of organelle degeneration. An increased number of secretory granules appeared in the apical regions of the principal cells. Gland cells that were not present in control epithelia appeared after 4 weeks. Cholesterol crystals began to appear by 4 weeks in the gallbladder bile and small cholesterol stones were found after 8 weeks. By 4 to 8 weeks, the muscularis had also thickened. The epithelial volume density increased from the normal 34% to 41.5% ($p < 0.05$) after 2 weeks, and to 44% after 8 weeks ($p < 0.001$). The number of clear cells or degenerate primary cells also increased. Increased exocytotic discharge of secretory products indicated a greater synthesis and release of glycoproteins into the bile. It is suggested that glycoproteins may be involved in trapping cholesterol crystals.

6085 EFFECT OF PHYSICAL EXERCISE ON ERYTHROCYTE LIPIDS, BILIARY CHOLESTEROL AND BILE LITHOGENICITY IN RATS.

(Eng.) Simko, V.; Kelley, R. (Univ. Cincinnati Medical Center, Cincinnati, OH 45267). *Eur. J. Clin. Invest.* 7(4):319-320; 1977.

The effects of physical exercise on liver and biliary cholesterol, on cholesterol solubility, and on RBC lipids were studied in male Wistar rats. Rats were exercised (E) by daily 1 hr swimming for 24 days. Sedentary controls (S) were caged individually. Bile analysis at the end of the experiment (24 hr after the last exercise) showed a decrease in bile cholesterol (0.78 ± 0.07 versus 1.27 ± 0.17 μmol/ml, $p<0.02$) and phospholipids (4.95 ± 0.42 versus 7.08 ± 0.53 μmol/ml, $p<0.01$) in the exercising animals, but no significant change in the bile acids. These changes in the exercising rats resulted in a decreased cholesterol saturation of bile (44.4 ± 3.4% versus 57.2 ± 7.4%, not significant), and in an improvement in the bile acid + phospholipid/cholesterol ratio (51.4 ± 4.9 versus 35.0 ± 5.9). Exercise did not affect the bile flow or bile acid flux rate. Exercise decreased RBC phospholipids ($p<0.01$). The effect of exercise on bile was associated with a trend to lower cholesterol in the RBC and in the adipose tissue and probably does not represent a shift of cholesterol from the liver to the peripheral tissues. Physical exercise may be a preventing factor in cholesterol gallstone formation.

6086 MECHANISM OF RAT LIVER MICROSOMAL MONO-OXYGENASE INHIBITION UNDER CHOLESTASIS DEVELOPMENT.

(Rus.) Zakharova, N. E.; Pospelova, L. N.; Gromova, O. A.; Tsyrlov, I. B.; Lyakhovich, V. V. (Inst. Clinical and Experimental Medicine, Novosibirsk, USSR). *Vopr. Med. Khim.* (2):181-185; 1977.

The changes of liver mono-oxygenase activity were studied in male Wistar rats subjected to ligation of the biliary duct. On days 4, 7, and 10 after surgery, rats were sacrificed, and the liver microsome fraction was isolated by ultracentrifugation. On day 4 after ligation, there was almost a twofold decrease in cytochrome P-450 content, a significant decrease of NADPH-cytochrome P-450 reductase activity, and a nonsignificant alteration of enzymatic peroxide lipid oxidation (PLO). Further accumulation of the bile acids in the liver of the cholestatic rats resulted in decreased enzymatic PLO on day 7, and decreased nonenzymatic PLO on day 10. The results of *in vitro* incubation of microsome fraction with sodium deoxycholate confirm the hypothesis that observed changes in xenobiotic metabolism in the cholestatic rats are due not to the cholic acid accumulation, but rather to the accumulation of the intermediate products of cholesterine oxidation.

6087 SIMULTANEOUS PROTECTIVE EFFECT OF A NEW CHELATING AGENT AND ZINC, ON THE CARBON TETRACHLORIDE INDUCED HEPATIC INJURY IN SQUIRRELS.

(Eng.) Rana, S. V. S. (Dept. Zoology, D. A. V. Coll., Muzaffarnagar-251001, India). *Res. Exp. Med. (Berl.)* 170(3):217-227; 1977.

Zinc and a chelating agent (para-amino salicylic acid oxine azo dye complex) were studied to evaluate their efficacy in overcoming liver damage caused by carbon tetrachloride administration to squirrels. Six groups of six squirrels each were used. Carbon tetrachloride (0.1 ml/100 g, i.p.) was given to groups 2, 3, and 4 on alternate days for 30 days. Zinc acetate (5.0 mg/100 g, by gavage) was administered to groups 3, 4, and 6 each day for the last 15 days of the study. The chelating agent (0.2 ml of a 0.2% solution/100 g, i.p.) was injected into groups 4 and 5 on days alternate to the CCl_4 injections during the last 15 days of the study. The histological changes caused by CCl_4 include the vacuolization of centrilobular parenchymal cells, the appearance of binucleated cells followed by the formation of balloon cells with clear cytoplasm and retracted nuclei; and general necrosis follows. Zinc given with CCl_4 maintained some cellular structure, but zinc and chelator, after 20 days of treatment, caused the appearance of rapidly regenerating areas with a diminished necrosis and, after 30 days of treatment, no differences were seen between the latter group and the controls. Squirrels receiving zinc and chelator showed histologic loss of much more accumulated fat and the presence of normal rather than elevated quantities of collagen when compared to carbon tetrachloride treated animals. The total activity of bound β-glucuronidase, the proportion of free β-glucuronidase, and the activity of glucose-6-phosphate dehydrogenase were altered by carbon tetrachloride treatment; these alterations were largely alleviated by zinc treatment and virtually normalized by the combined therapy of zinc and chelator. The chelator assisted in removing excess zinc, as noted when group 3 was compared to group 4 (97.8 ± 7.40 and 89.7 ± 7.06 μg zinc/g dry weight liver, resp.). The author suggests that the chelating agent should be considered for clinical utilization even though the agent's mechanism of action remains largely unknown.

6088 PREVENTION BY CHLORPROMAZINE OF ISCHEMIC LIVER CELL DEATH.

(Eng.) Chien, K. R.; Abrams, J.; Pfau, R. G.; Farber, J. L. (Temple Univ. Sch. Medicine, 3400 N. Broad St., Philadelphia, PA 19140). *Am. J. Pathol.* 88(3):539-554; 1977.

The protective action of chlorpromazine against ischemic liver cell death was studied. Ischemic liver tissue was produced by clamping the portal venous and hepatic arterial blood supply to the left lateral and median lobes of rat liver. If, after 2-3 hr of ischemia, reflow to the liver was established by removing the clamp, two-thirds or more of the liver cells were histologically dead 24 hr later. Pretreatment with chlorpromazine (20 mg/kg) 30 min before inducing ischemia for up to 3 hr prevented this ischemic cell death. If the animals were kept alive for an additional 24 hr with no further treatment, the extent of liver cell necrosis at 48 hr was still markedly less than that seen in the untreated ischemic controls. Administration of chlorpromazine, after induction of ischemia and immediately prior to the onset of reflow, reduced but did not completely prevent ischemic cell death as determined at 24 hr. This protective action of chlorpromazine was confirmed by the ability of the treated animals to regenerate cellular ATP levels after 3 hr of ischemia. In addition, chlorpromazine significantly reduced the increases in total liver cell and mitochondrial calcium ion contents that accompanied the return of blood flow to irreversibly injured liver cells. The protective effect of chlorpromazine was not attributed to any effect either on the rate or extent to which the liver cells became ischemic or on the perfusion patterns following release of the obstruction. It is concluded that the action of chlorpromazine must be on some component(s) of the reaction of the cells to the ischemia itself.

6089 THE EFFECT OF GAMMA-HEXACHLORCYCLOHEXANE ON RAT LIVER LYSOSOMES.

(Eng.) Carevic, O. (Pharmaceutical and Chemical Works, 41000 Zagrab, I. L. Ribara 89, Yugoslavia). *Biochem. Pharmacol.* 26(15):1377-1381; 1977.

A study was undertaken to investigate whether hepatic cell necrosis and increased activity of serum acid phosphatase observed previously in gamma-hexachlorcyclohexane-intoxicated rats are causally related to the alterations of liver lysosomal membranes. Experimental and control groups of 25 male and female Wistar rats each received an i.p. injection of gamma-HCH (40 mg/kg, LD_{50}); five rats were sacrificed at 1, 4, 8, 12, and 24 hr post injection, and their liver lysosomal hydrolase activities were measured. Gamma-HCH induced a significant release of three lysosomal enzymes--acid phosphatase, β-glucosidase, and cathepsin D--in rat livers at only 1 hr after administration of the agent. From 1 hr up to 24 hr of the observation period, release of selected lysosomal hydrolases consistently increased. Morphological changes, including hepatic necrosis and fatty infiltration, were established later at 24 hr after gamma-HCH treatment. The *in vitro* studies on the latency of two lysosomal enzymes--acid phosphatase and β-glucosidase--in the rat liver lysosome-rich suspension treated with gamma-HCH, showed that concentrations of $\geq 10^{-5}$ M significantly decreased the latency of both enzymes. However, acid phosphatase and β-glucosidase exhibited differential responses *in vitro* to the effect of gamma-HCH, which might be due to the differential affinities of these enzymes for the lysosomal matrix. Concentrations of gamma-HCH of $>10^{-5}$ M did not significantly alter the activities of acid phosphatase, β-glucosidase, and cathepsin D *in vitro*. No significant changes were observed in the total activities of enzymes studied after *in vivo* and *in vitro* administered gamma-HCH. The results suggest that gamma-HCH exerts its effect on rat liver lysosomes by modifying the lysosomal membrane's structural properties.

6090 HEPATIC LESIONS AND HEMOLYSIS FOLLOWING ADMINISTRATION OF 3α, 7α, 12α-TRIHYDROXY-5β-CHOLESTAN-26-OYL TAURINE TO RATS.

(Eng.) Hanson, R. F.; Williams, G. C.; Hachey, D.; Sharp, H. L. (Box 23 Mayo, Univ. Minnesota Hosp., Minneapolis, MN 55455). *J. Lab. Clin. Med.* 90(3):536-548; 1977.

The effects of taurine conjugated 3α, 7α, 12α-trihydroxy-5β-cholestan-26-oyl (tauro-THCA) on hemolysis, bile flow, and hepatic morphology were evaluated in bile fistula rats to determine if increased amounts of conjugated THCA causes liver disease and hemolysis in patients with a metabolic block in the conversion of THCA to cholic acid. All rats infused with tauro-THCA at rates of 0.25, 0.50, or 0.75 μmol/min developed hemolysis with hemoglobinuria. A direct toxic effect of tauro-THCA on washed human RBC membranes was demonstrated at a concentration of 8×10^{-4} M. Liver biopsy sections from rats infused for a 2-hr period with tauro-THCA were examined by electron microscopy and showed dilation of the rough endoplasmic reticulum and distortion of mitochondrial membranes. Cholestasis was not induced, since tauro-THCA actually caused a greater choleretic response for a given rate of bile salt excretion than did taurocholate. This study supports the contention that the clinical liver disease seen in patients with a metabolic block in the conversion of THCA into cholic acid may be caused by tauro-THCA.

6091 STIMULATION OF HEPATOCELLULAR PROLIFERATION BY A SERUM FACTOR FROM THIOACETAMIDE-TREATED RATS.

(Eng.) Morley, C. G. D.; Boyer, J. L. (Dept. Medicine, Univ. Chicago, 950 East 9th St., Chicago, IL 60637). *Biochim. Biophys. Acta* 477 (2):165-176; 1977.

Humoral DNA synthesis-stimulating factors in the sera of thioacetamide-treated male Sprague Dawley rats were investigated by studying the responses to these sera in male CF_1 mice. Thioacetamide (25, 50, 100, and 200 mg/kg) was given to groups of five rats each and blood was collected at 6, 18, and 72 hr. Donor rats showed liver centrilobular and periportal necrosis following administration of 50 mg/kg thioacetamide; hepatic DNA synthesis began to rise by 24 hr and was maximal at 36 hr. Administration of ^3H-thymidine (1 μCi/g body weight, i.p.) showed peak liver DNA synthesis stimulation in CF_1 mice following injection of sera obtained from rats 48 hr after 50 mg/kg thioacetamide administration. Aliquots of 0.02, 0.05, 0.075, 0.10, and 0.20 ml serum were tested in a dose versus response experiment on mice; 0.1 ml (6 mg protein) serum gave the maximal response, which consisted of a 10-fold increase in mitosis, a 6-fold increase in the percentage of labeled nuclei, and a 2-fold increase in DNA synthesis. Dialysis or boiling and dialysis did not affect DNA synthesis stimulation, but these treatments halved the effects on mitosis and thymidine-labeled nuclei. The results suggest that humoral growth factors might play a role in hepatic repair after chemical insult.

Intestine

6128 STIMULATION BY IMMUNE COMPLEXES OF MUCUS RELEASE FROM GOBLET CELLS OF THE RAT SMALL INTESTINE. (Eng.) Walker, W. A.; Wu, M.; Bloch, K. J. (Massachusetts General Hosp., Boston, MA 02114). *Science* 197(4301):370-372; 1977.

The ability of immune complexes to stimulate mucus release was studied in female Sprague-Dawley rats. Immune complexes (bovine serum albumin with rat antibodies to bovine serum albumin) formed in twofold antibody excess were injected into the duodenum of normal rats. In comparison to controls injected with antigen only, there was a marked increase in the percentage of disrupted goblet cells (an index of mucus release) in segments from the intestine of rats exposed for 3 hr to immune complexes *in vivo* ($p<0.001$). Similarly, there was a significant increase in ^{35}S-labeled mucus recovered by filtration of intestinal wash, rinse, and mucosal homogenate fluids from rats exposed to immune complexes compared to those from rats exposed to bovine serum albumin or purified rat antiserum to bovine serum albumin alone. These findings suggest that certain immune complexes can stimulate mucus release from intact rat small intestine; enhanced mucus release may have a role in clearing the surface of these complexes.

6129 ELECTRON MICROSCOPIC DETECTION OF CALCIUM BINDING TO THE DUODENAL ABSORPTIVE CELL PLASMA MEMBRANES. (Eng.) Jande, S. S. (Dept. Anatomy, Univ. Ottawa, Ottawa, Ontario, Canada K1N 9A9). *Anat. Embryol.* 150(2):155-162; 1977.

Calcium binding was studied ultrastructurally in chick duodenal loops. This material was fixed at 2 days before hatching, 2 days after hatching, and 4 weeks after hatching with the chicks on a normal diet, 4 weeks after hatching with the chicks on a vitamin D-deficient diet, 5 weeks after hatching with the chicks on a vitamin D-deficient diet supplemented with p.o.-administered vitamin D_3 (500 IU) for the last week, and 4 weeks after hatching with the chicks on a vitamin D-deficient diet supplemented with *Cestrum diurnum* leaves for the last week. Electron dense structures (EDS) were observed on the plasma membranes of duodenal absorptive cells of some chicks. EDS were seen only when calcium was added to formal glutaraldehyde fixative in cacodylate buffer and the material was postosmicated in phosphate buffer. Microvillar, lateral, and basal plasma membranes showed the EDS, and these were seen always in the inner dark layer of the three-layered unit membrane. No EDS were seen in the embryonic material, but some were present in material from chicks 2 days after hatching. There were more EDS in material from 6-week-old normal and vitamin D-replete animals. The absorptive cells from chicks fed *Cestrum* powder (known to mimic the effects of 1,25-dihydroxycholecalciferol) showed the highest number of EDS. The distinct correlation of EDS frequency with amounts of calcium binding protein known to be present in chick duodenum suggests that the site of calcium binding protein is the EDS.

6130 LACTASE LEVELS IN THE INTESTINES OF THE YOUNG OF PROTEIN-DEFICIENT RATS. (Eng.) Mahboob, S.; Zeman, F. J. (Dept. Nutrition, Univ. California, Davis, CA 95616). *Nutr. Rep. Int.* 15(4):451-457; 1977.

The effect of prenatal protein deficiency (PPD) on elevated lactase activity in neonatal rat intestine was investigated together with the effect of age on lactase activity decline and whether proximal, medial, and distal segments of the intestine differ in lactase activity. Pregnant Sprague-Dawley rats were fed diets either of 24% casein (controls) or of 4% casein with an additional 20% glucose (experimental, protein-deficient) during gestation. Suckled newborn pups and 17-, 19-, and 21-day-old pups of these mothers were examined. Mean body (6.40-3.54 g) and intestinal (166.11-77.52 mg) weights were significantly lower both in suckled neonates ($p< 0.001$) and in all postnatal pups ($p< 0.001$) compared to controls. The intestinal/body weight ratio also showed significant reduction (from 25.89 to 21.72 mg/g) in PPD newborns when compared to controls, but was not significantly different in older postnatal pups. Lactase activity significantly increased ($p< 0.001$) in proximal and distal but not medial segments compared to controls. No significant differences between control and PPD pups of matching ages were observed with respect to lactase activity in various segments in 17-, 19-, and 21-day-old rats, except for 19-day PPD distal segments. Newborn PPD pups showed no difference in lactase activity among various segments when compared to controls. Lactase activity fell with age in all segments. It is concluded that PPD affects the entire intestine and that the elevated lactase levels at birth might be due to retardation of intestinal maturation caused by depressed thyroid function in these animals.

6131 BIOSYNTHESIS OF GLYCOPROTEINS IN THE INTESTINAL MUCOSA. I. SOLUBLE STATE OF FIVE GLYCOSYL-TRANSFERASES. (Eng.) Martin, A.; Louisot, P. (Univ. Lyon, Lyon-Sud Medical Sch., 69600 Oullins, France). *Int. J. Biochem.* 7(9/10): 501-505; 1976.

The activities of five glycosyl transferases in mitochondrial, microsomal, or cytosol fractions of rat small intestinal mucosa were evaluated using endogenous and exogenous acceptors to determine their distribution, solubility, and stabilities. Acellular incorporation of radioactive nucleoside-diphospho-sugars into glycoproteins was measured, and the identity of the transferred sugar was determined by hydrolysis and chromatography. Assays with endogenous acceptors indicated that sialyl and galactosyl transferase activities were primarily located in the microsomal fraction (70% and 80% activity, resp.), while fucosyl transferase activity predominated in the mitochondrial (59%) and microsomal (30%) fractions. Mannosyl and *N*-acetyl galactosamine transferase activities were found in the mitochondrial (28% and 45%, resp.) and cytosol (63% and 45%, resp.) fractions, while *N*-acetyl glucosamine transferase activity was primarily located in the cytosol (80%). However, use of the appropriate exogenous acceptor showed high levels of sialyl, galactosyl, fucosyl, and mannosyl transferase activities in the cytosol (62%, 71%, 71%, and 74%, resp.). Each of the incorporated sugars was found in the form in which it had been added to the medium except mannose, of which 95% had been converted to fucose. The transferases were relatively stable to purification and in storage. Contaminants of membrane origin in each fraction indicated that the transferases are solubilized membrane enzymes. The solubility and stability of cytosolic glycosyl transferases improve the prospects for their purification and study.

GENERAL

6142 MICROCIRCULATION OF THE RAT SMALL INTESTINE AS STUDIED BY THE INJECTION REPLICA SCANNING ELECTRON MICROSCOPE METHOD. (Eng.) Ohashi, Y.; Kita, S.; Murakami, T. (Okayama Univ. Sch. Medicine, Okayama, 700 Japan). *Arch. Histol. Jpn.* 39 (4):271-282; 1976.

Mucosal blood supply in the rat intestine was studied by the injection replica scanning electron microscope method. The vessels of the vascular plexus originate at the tip of the villus and converge near the base of the villus. This demonstrates the existence of the previously described "fountain pattern" of the villus microcirculation. The capillary plexus in the crypt is derived at the base of the crypt and converges near the base of the crypt. The capillary plexuses in the villus and the crypt communicate with each other. The basal segments of the villus, where the arterial termination is lacking, is thought to be supplied by the cryptal capillaries via this communication.

6143 COMPARISON OF PORTAL FLOW DISTRIBUTION AFTER PORTACAVAL AND MESOCAVAL SHUNTS. (Eng.) Harmon, J. W.; Zinner, M. J.; Reynolds, D. G. (Walter Reed Army Inst. Res., Walter Reed Army Medical Center, Washington, DC 20012). *J. Surg. Res.* 22(4):343-347; 1977.

Gamma-labeled radioactive microspheres were injected into the superior mesenteric vein, the inferior mesenteric vein, and the splenic vein of normal dogs to compare the distribution of portal blood flow after the construction of either side-to-side portacaval (SSP) or interposition mesocaval (IM) shunts. To clarify the difference between these two shunts further, a group of dogs in which interposition portacaval (IP) shunts were constructed was also studied. Depending on the microsphere injection site, control experiments (no shunt) demonstrated that between 99.8 ± 0.1 and 99.9 ± 0.1% of the injected microspheres lodged in the liver. The SSP shunt functioned as a total systemic shunt, with the percentage of microspheres lodged in the liver ranging from only 0.03 ± 0.02 to 1.4 ± 1.2%, depending on the injection site; the remaining microspheres lodged in the lung. In contrast, the IM shunt resulted in definite preservation of portal hepatic blood flow, with the highest proportion of blood flow to the liver coming via the splenic vein (70.2 ± 12.7%) and the least via the superior mesenteric vein (31.2 ± 19.5%). The percentage flow in the inferior mesenteric (62.0 ± 20.4%) and splenic veins was significantly greater ($p<0.05$) after the IM shunt than after the SSP shunt. Preservation of some hepatic blood flow was also observed with the IP shunt; the superior mesenteric (22.6 ± 7.3%) and inferior mesenteric (25.2 ± 1.0%) venous flow distributions after the IP shunt were both significantly different ($p<0.05$) from the distribution after the SSP shunt. There was no significant difference between the IM and IP shunts. Based on these findings, the use of a SSP shunt to preserve portal hepatic blood flow in cirrhotic patients is completely unjustified. Whether the IM shunt would preserve hepatic blood flow in cirrhotics with elevated portal pressure cannot be determined from these studies.

6144 IMMUNOPROPHYLAXIS AND THERAPY OF GRAFTED RAT COLONIC CARCINOMA. (Eng.) Martin, M. S.; Martin, F.; Justrabo, E.; Michel, M. F.; Lagneau, A. (Laboratoire d'Immunologie, Faculte de Medecine, Dijon, France). *Gut* 18(3):232-235; 1977.

Two independent lines of chemically-induced colonic carcinoma, serially graftable in syngeneic rats, were used to investigate the effects of immunoprophylaxis and immunotherapy. BD-IX strain rats were challenged s.c. with 2×10^6 DHD or DHB carcinoma cells. Only one of four protocols resulted in a partial inhibition of tumor growth: in this experiment, *Mycobacterium bovis*, strain BCG, was used as an immunostimulating agent. Six of eight rats challenged on the same day as the administration of 9.5 mg of BCG were tumor-free at the end of the experiment (56 days after challenge), which was a significantly lower tumor frequency ($p<0.007$) than that of the untreated challenged controls (0/8 tumor-free animals). The mean tumor weight was significantly lower in the two tumor-bearing rats in the BCG-treated group ($p<0.01$) than that in the controls. The mean tumor weight was also significantly lower ($p<0.05$) in rats treated with BCG 15 days after challenge. Significant enhancement of tumor growth was observed in two protocols in which tumor cells, or tumor cells plus BCG, were used for immunostimulatory therapy; the tumors were approximately seven times larger in treated animals than in controls. The tumor incidence in rats that received mitomycin- and neuraminidase-treated DHD cells for immunostimulatory therapy (5/8) was the same as that in controls, and the mean tumor weights in the two groups was not significantly different. The data emphasize the potential hazards of tumor enhancement in the immunotherapy of human colorectal cancer.

6145 STUDIES ON IMMUNE RESPONSES TO LARVAL CESTODES IN MICE: IMMUNOGLOBULINS ASSOCIATED WITH THE LARVAE OF Mesocestoides corti.

(Eng.) Mitchell, G. F.; Marchalonis, J. J.; Smith, P. M.; Nicholas, W. L.; Warner, N. L. (Walter and Eliza Hall Inst., Royal Melbourne Hosp., P.O., Victoria 3050, Australia). *Aust. J. Exp. Biol. Med. Sci.* 55(2):187-211; 1977.

Mesocestoides corti was investigated in terms of the immunological aspects of the host-parasite relationship. Hypothymic BALB/c.nu/nu ("nude") mice (short-term infected, 21 days) were more susceptible (number of liver larvae at day 21, mean 956) than their intact BALB/c.nu/+ littermates (short-term infected; number of liver larvae at day 21, mean 73) to infection with *M. corti*, and antigens of this parasite induced T cell-dependent immune responses in intact mice. Defective anti-dinitrophenol (DNP) antibody responses were induced by DNP-*M. corti* larvae and DNP-human gamma globulin (HGG) in infected intact mice. However, on transfer to uninfected irradiated recipients, lymphoid cells from infected intact mice responded well to DNP-*M. corti* larvae. Surface immunoglobulin content of peritoneal *M. corti* larvae from long-term infected mice (injected with larvae 2-6 months previously), determined by the ability of a 50 μl washed pellet of larvae to absorb anti-Ig antibodies was IgG$_1$, 0.81 ± 0.11 μg; IgM, 0.35 ± 0.10 μg; IgG$_{2a}$, 0.03 ± 0.01 μg; IgG$_{2b}$, 0.07 ± 0.02 μg; IgG$_3$, 0.11 ± 0.03 μg; and IgA, <0.05 μg. IgM (0.09 ± 0.04 μg) predominated in BALB/c.nu/nu-derived larvae. Chronically infected intact mice contained large amounts of IgG$_1$ immunoglobulins in their serum. Very few proteins were available for labeling on peritoneal larvae by the lactoperoxidase-catalyzed radioiodination technique. IgG$_1$ molecules (concentration in original sample, 11.0 μg/ml; after absorption with treated larvae, 2.2-3.8 μg/ml) associated with *M. corti* larvae for long-term infected mice were reported to include antiparasite antibodies. However, no clear cut evidence is available to show whether the *M. corti*-associated immunoglobulins (and in particular IgG$_1$, which is reported to be relatively inert with respect to direct pathogenic effects) serves the function of masking parasite antigens and protecting the established parasites from more aggressive T cell-dependent immunological effector mechanisms.

6146 THE EFFECT OF LASER PHOTOCOAGULATION ON THE GASTRIC MUCOSA AND BLEEDING GASTRIC LESIONS.

(Eng.) Bank, S.; Miles, A. E.; Botha, J. B. C. (Groote Schuur Hosp., Capetown, S. Africa). *S. Afr. Med. J.* 52(9):347-350; 1977.

An argon ion laser beam was tested experimentally for its histological effect on and penetration of the gastric mucosa of rat and man and for its ability to induce hemostasis in traumatically produced gastric lesions and transected small blood vessels. Lesions were made in the gastric mucosa of 40 Long-Evans anesthetized rats producing two ulcers in each; one for photocoagulation and one to serve as a control. Localized laser photocoagulation lasting from 2 sec to 5 min at 1 W produced a coagulative necrosis of the gastric mucosa and half of the muscularis propria. Transmural necrosis required prolonged exposure of 10-15 min for rat stomach and 20-30 min for human stomach. Laser phototherapy markedly reduced the bleeding time in experimental ulcers and small blood vessels by 50-100%, provided the superficial blood could be adequately dispersed from the direct beam of the laser.

DIAGNOSTIC PROCEDURES

6151 COMPARISON OF ULTRASOUND PANCREATIC SCANNING AND ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAMS: A RETROSPECTIVE STUDY. (Eng.) Feinberg, S. B.; Schreiber, D. R.; Goodale, R. (Box 292-Mayo, Univ. Minnesota Hosp., Minneapolis, MN 55455). *J. Clin. Ultrasound* 5(2):96-100; 1977.

The results of ultrasound pancreatic scanning and of endoscopic retrograde cholangiopancreatography (ERCP) were compared in 32 patients who underwent both procedures for the diagnosis of pancreatic diseases. Thirty-one ultrasound studies were satisfactory, and ERCP cannulation was possible in 26 cases. Among the 11 patients with pancreatitis, the correct diagnosis was suggested by the results of ultrasound in 10, and by ERCP in 7. Pancreatic pseudocyst was correctly diagnosed by ultrasound in all of four patients and in three of the four by ERCP. Among the 10 patients with pancreatic or periampullary carcinoma, the correct diagnosis was made by ultrasound in 9 and by ERCP in 5. The overall success for ultrasound pancreatic scanning was 93.8%, and the overall success for ERCP cannulations was 62.5%. Ultrasonography provides a safe screening procedure with a high overall accuracy rate in the diagnosis of pancreatic diseases. ERCP provides a complementary approach for evaluating small lesions and aids in defining surgical lesions.

6152 DETECTION OF GALLBLADDER DISEASE IN PATIENTS WITH NORMAL ORAL CHOLECYSTOGRAMS: RESULTS USING A SIMPLIFIED BILIARY DRAINAGE TECHNIQUE. (Eng.) Foss, D. C.; Laing, R. R. (Univ. Kansas Medical Center, Kansas City, KS 66102). *Am. J. Dig. Dis.* 22(8):685-689; 1977.

The value of biliary drainage in the diagnosis of gallbladder disease was studied in 70 patients with histories suggestive of gallbladder disease but with normal oral cholecystograms. Of the 29 patients with abnormal drainage studies, 26 had cholecystectomy; all specimens showed cholecystitis, and cholelithiasis was seen in 46%. Five of the 41 patients with normal drainages underwent cholecystectomy, but no abnormality was noted in any surgical specimen. Significant differences were seen when the mean WBC count, frequency of leukocytosis, and the presence of back pain were compared between the normal and abnormal drainage groups. Biliary drainage is a useful supplemental test when a false-negative oral cholecystogram is suspected.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6198 A PROSPECTIVE, RANDOMISED STUDY OF ENDOSCOPY AND RADIOLOGY IN ACUTE UPPER-GASTROINTESTINAL-TRACT BLEEDING. (Eng.) Dronfield, M. W.; Ferguson, R.; McIllmurray, M. B.; Atkinson, M.; Langman, M. J. S. (City Hosp., Nottingham NG5 1PB, England). *Lancet* 1(8023):1167-1169; 1977.

The value of emergency endoscopy was compared with that of radiology in a prospective, randomized investigation of 318 patients hospitalized with acute upper gastrointestinal bleeding. Although the diagnostic yield was higher in the endoscopy group (108/162) than the radiology group (88/160), there was no difference between the two groups in management or survival, and the accuracy of the findings, as judged independently at operation and/or autopsy, was also similar in the two groups. These findings cast doubt on the need to provide emergency endoscopic facilities for the investigation of patients with acute upper gastrointestinal bleeding where radiological services are already adequate.

6199 RADIOLOGIC TREATMENT OF ESOPHAGEAL FOOD IMPACTION USING INTRAVENOUS GLUCAGON. (Eng.) Ferrucci, J. T., Jr.; Long, J. A., Jr. (Massachusetts General Hosp., Boston, MA 02114). *Radiology* 125(1):25-28; 1977.

The cases of three patients in whom esophageal food impaction was successfully treated using i.v. glucagon are presented. These patients were among six given 1.0 mg of glucagon; food impaction persisted in the remaining three. The patients who were successfully treated had impaction for 1-3 days before presentation. In all cases, barium swallow 15 min after glucagon administration revealed that the food bolus had passed with complete clearing of the esophageal lumen. Since proteolytic enzyme digestion of bolus impaction carries a clear risk of fatal esophageal perforation, early therapeutic administration of glucagon during the initial esophagography affords a safe and effective acute-care radiologic adjunct.

6200 PROGNOSTIC SIGNIFICANCE OF PORTAL PRESSURE IN PATIENTS WITH BLEEDING ESOPHAGEAL VARICES. (Eng.) Adamsons, R. J.; Butt, K.; Dennis, C. R.; Kinkhabwala, M.; Moskowitz, H.; Gordon, D.; *et al.* (Downstate Medical Center, Brooklyn, NY). *Surg. Gynecol. Obstet.* 145(3):353-356; 1977.

Portal pressure was determined in 76 patients during the acute bleeding episode of hemorrhagic varices, and the degree of portal hypertension was related to the cessation or noncessation of hemorrhage with nonoperative management. Portal pressure was determined by hepatic vein wedge catheter in 40 patients, by splenic puncture in 19, intraoperatively in 11, and by percutaneous transhepatic portal vein cannulation in 6. Hemorrhage was arrested nonsurgically in 38 patients and had to be treated surgically in the remainder; the age range of the two groups was similar, 45.3 yr and 45.0 yr, resp. To compare the outcome of hemorrhage with the degree of portal hypertension, all patients were divided into subgroups, with increments in portal pressure of 3 cm of saline solution in each subgroup. No patient with portal pressure less than 17 cm of saline solution had documented bleeding from esophageal varices. While the cessation of hemorrhage in patients with a portal pressure of 27-33 cm was 100% with conservative treatment, there was a decreasing percentage of cessation of hemorrhage in each subgroup with increasing portal pressure: 65, 46.7, 38.5, 25.0, 16.7, and 0%, resp., for each 3 cm rise in pressure. The last group, in which 0% of the patients could be treated conservatively, consisted of five patients with pressures of 49-54 cm saline. These data were statistically significant ($p<0.001$). The results indicate that there is a direct relation between the severity of hemorrhage and the degree of portal hypertension. Portal pressure should be determined as soon as feasible when bleeding varices are suspected, and other causes of hemorrhage should be carefully excluded. The data are of great prognostic significance and might be helpful in planning the course of therapy in these patients.

6224 GASTRIC EMPTYING IN DIABETIC AUTONOMIC NEUROPATHY.

(Eng.) Campbell, I. W.; Heading, R. C.; Tothill, P.; Buist, T. A. S.; Ewing, D. J.; Clarke, B. F. (Royal Infirmary, Edinburgh, Scotland). *Gut* 18(6):462-467; 1977.

Gastric emptying was studied in six diabetic patients with and six without objective evidence of autonomic neuropathy, using a double isotope scintiscanning technique, which differentiated between solid and liquid emptying. Gastric stasis was observed in three of the patients with autonomic neuropathy, although this was detected by conventional radiology (barium examination) in only one of these three patients. The half-time values for liquid marker emptying in the three patients with gastric stasis were 106, 103, and 205 min, compared with a nondiabetic control value of 39 ± 12 min. The other three patients with autonomic neuropathy exhibited normal gastric emptying half-time values (range, 26-52 min) as did the six diabetics without autonomic neuropathy (range, 20-52 min). Neither patients with stasis nor those without stasis exhibited abnormally rapid early gastric emptying. Whereas nondiabetic control subjects exhibited clear differences in emptying patterns of liquid and solid markers (solids emptying more slowly than the liquid), the patterns of solid and liquid marker emptying in diabetics were much more alike, and there was no statistically significant difference between them. Both i.v. and p.o. metoclopramide (10 mg) produced symptomatic improvement in two patients with gastric stasis and restored their gastric emptying to normal.

6225 GASTRIC COMPLICATIONS AFTER RADIOTHERAPY FOR HODGKIN'S DISEASE AND OTHER LYMPHOMAS.

(Eng.) Kellum, J. M., Jr.; Jaffe, B. M.; Calhoun, T. R.; Ballinger, W. F., II. (Tufts Univ. Sch. Medicine, 171 Harrison Ave., Boston, MA 02111). *Am. J. Surg.* 134(3):314-317; 1977.

The cases of six patients (17-63 yr; average, 39 yr) who developed gastric complications after radiotherapy for lymphomas are reported. Three patients received radiation therapy for Hodgkin's disease, two for primary gastric lymphomas, and one for generalized lymphosarcoma. The complications occurred from 2 months to 11.5 yr (median, 3 months) after irradiation, and all patients received a cumulative dose of at least 4,500 rads. The first patient received a cumulative irradiation dose of 17,500 rads, of which more than 6,000 rads was directed to the upper abdomen. She developed a gastrocolic fistula 12 months later, which was successfully treated by subtotal gastrectomy, gastrojejunostomy, and resection of the involved portion of transverse colon. The second patient received a total dose of 4,550 rads to the epigastrium. Esophagogastrectomy, vagotomy, pyloroplasty, and splenectomy were carried out 2 months after the last dose for the removal of what was found to be a radiation pseudotumor. The third patient developed a large perforating gastric ulcer 3 months following a total dose of 8,000 rads. Two months following a total dose of over 4,500 rads, the fourth patient developed gastric ulceration. The fifth patient developed radiation gastritis 2 months following 4,000 rads total nodal radiation, and the sixth patient developed a pyloric stricture 138 months following a total dose of 5,700 rads. Gastric resection with gastrojejunostomy was the surgical treatment in the last four cases. In most cases, the symptoms of radiation injury mimicked those of recurrent neoplastic disease.

6226 MUCOSAL CHANGES IN THE GASTRIC STUMP 20-25 YEARS AFTER PARTIAL GASTRECTOMY.

(Eng.) Schrumpf, E.; Stadaas, J.; Myren, J.; Serck-Hanssen, A.; Aune, S.; Osnes, M. (Ulleval Hosp., Oslo, Norway). *Lancet* 2(8036):467-469; 1977.

The value of routine endoscopy combined with multiple biopsies in patients with gastric resection was evaluated in 108 patients who underwent Billroth type-II gastrectomy 20-25 yr previously. In no case were the endoscopic appearances of the mucosae interpreted as malignant, although in two patients the clinical history suggested malignant disease. The histological examination revealed infiltrating carcinoma in four patients, three of whom had intramucosal carcinoma only. Three further patients had severe dysplasia (carcinoma *in situ*). Only one patient had a near-normal mucosa close to the anastomosis; in the remainder the gastric remnant showed various degrees of dysplasia, metaplasia, or chronic atrophic gastritis. In the patients with carcinoma only, 28 of the 226 biopsy specimens revealed the malignant lesion. Patients who have had partial gastrectomy for benign lesions are at high risk of gastric stump carcinoma. If endoscopy with multiple biopsy is carried out 20 yr after resection, stump carcinoma may be detected when the prognosis after operation is probably good.

6227 BARIUM MEAL APPEARANCE SIMULATING SUPERFICIAL ULCERATION.

(Eng.) Gould, S. R.; Frank, P.; Davison, L.; Bogomoletz, W. V.; Barnardo, D. E. (St. Mark's Hosp., City Rd., London EC1V 2PS, England). *Clin. Radiol.* 28(4):449-452; 1977.

The cases of five patients in whom a single contrast barium meal examination demonstrated diffuse gastric spiculation simulating superficial ulceration are summarized. The examination was carried out because of duodenal ulceration in two cases, gastroesophageal reflux in one case, and ileocolic Crohn's disease in one; gastroscopy prior to barium examination was normal in these four patients. The fifth patient had endoscopically and histologically confirmed gastritis. The results indicate that a barium meal spiculation pattern simulating widespread superficial mucosal ulceration may coexist with gastroscopically and histologically normal mucosa. This radiological appearance may be due to filling of the grooves between the areae gastricae and may thus represent a normal anatomical variant.

STOMACH

Peptic Ulcers

6261 ANTRAL GASTRIN AND ACID SECRETION IN DUODENAL ULCER PATIENTS. (Eng.) Perreault, C.; Coutsoftides, T.; Himal, H. S. (Dept. Experimental Surgery, McGill Univ., Montreal, Quebec, Canada). *Am. J. Surg.* 134(2):244-247; 1977.

The acid and gastrin responses to meat extract were studied in 12 normal subjects and in 51 duodenal ulcer patients before and after vagotomy-antrectomy or vagotomy and drainage. Two groups of ulcer patients were identified: antral responders (19 patients), in whom meat extract instillation led to at least a 50% increase in acid output, and antral nonresponders (32 patients), in whom meat extract instillation caused no significant response. The basal acid output was significantly greater in antral nonresponders than in antral responders (6.9 ± 0.8 versus 3.3 ± 1.1 mEq/l, $p<0.001$). Food-stimulated gastrin output was significantly greater in antral responders than in nonresponders (163.3 ± 6.6 versus 89.9 ± 9.7 pg/ml, $p<0.001$). Food-stimulated and peak acid outputs significantly decreased after vagotomy and drainage and after vagotomy-antrectomy in both responders and nonresponders. Basal acid output significantly decreased in the responders after vagotomy-antrectomy, but not after vagotomy and drainage. Basal and food-stimulated gastrin outputs decreased in the nonresponders after vagotomy-antrectomy. Basal and food-stimulated gastrin outputs increased after vagotomy and drainage in both responders and nonresponders, and food-stimulated gastrin output decreased after vagotomy-antrectomy in the responders. Differentiation of duodenal ulcer patients into antral responders and nonresponders allows for the selection of patients for specific surgery and may decrease the incidence of stomal ulceration and other complications, such as the dumping syndrome, after gastric surgery.

6262 LIGHT AND ELECTRON MICROSCOPICAL STUDIES OF PARIETAL CELLS BEFORE AND ONE YEAR AFTER PROXIMAL GASTRIC VAGOTOMY IN DUODENAL ULCER PATIENTS. (Eng.) Aase, S.; Roland, M. (Anatomical Inst., Univ. Oslo, Karl Johansgt. 47, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(4):417-420; 1977.

Parietal cell morphology was studied before and 1 yr after proximal gastric vagotomy (PGV) in four duodenal ulcer patients. The average basal gastric acid secretion of the patients was reduced from 9.2 mmol/hr before to 0.9 mmol/hr 1 yr after PGV (90% reduction). The reduction in acid secretion was not accompanied by changes in the morphology of the parietal cells. Light microscopy indicated that the average cell size was about the same before and 1 yr after PGV. Electron microscopy showed only negligible changes in the parietal cell ultrastructure.

6263 THE FUNCTIONAL STATE OF THE GASTROINTESTINAL TRACT AFTER ULCER SURGERY. A TEN-YEAR PROSPECTIVE FOLLOW-UP STUDY. (Eng.) Paakkonen, M.; Aukee, S.; Jussila, J. (Univ. Central Hosp., Kuopio, 70210 Kuopio 21, Finland). *Scand. J. Gastroenterol.* 12(5):599-603; 1977.

Absorption tests were carried out in 26 patients before and 1, 6, and 10 yr following surgery for peptic ulcer. The operations included antrectomy with gastroduodenostomy in 10, antrectomy with selective vagotomy and gastroduodenostomy in 9, and other operations in 7. None had recurrence of the ulcer or disturbing abdominal complaints during the follow-up period. Ten years after operation there was an increase in the mean value of the Schilling test, and all patients had a normal serum vitamin B_{12} level. The mean d-xylose excretion was decreased (1.3-3.1 g) in comparison with that before surgery (4.9-6.6 g), and fecal dry-weight fat content was increased. At the time of the 10th yr follow-up examination, six patients had impaired d-xylose absorption, and seven had impaired fat absorption. However, the increase in the mean body weight and the serum protein and hemoglobin concentration demonstrated that the nutritional status had not worsened.

6287 PRIMARY ADENOCARCINOMA OF THE SMALL INTESTINE. (Eng.) Morgan, D. F.; Busuttil, R. W. (Univ. California Los Angeles Sch. Medicine, Los Angeles, CA 90024). *Am. J. Surg.* 134(3):331-333; 1977.

The clinical features, pathology, and treatment of small bowel adenocarcinoma were studied in 18 cases. The median survival from the time of diagnosis was 10.5 months, with 55% of the patients dead of their disease within 24 months. There were no 5-yr survivors. Symptoms of obstruction were present in 72% of the patients, while pain, the most common symptom, occurred in 78%. Other common symptoms were weight loss (66%), gross or occult blood loss (33%), palpable mass (22%), and jaundice (11%). The origin of the tumor was fairly equally distributed among the duodenum (7 patients), jejunum (6), and ileum (5). The presumptive diagnosis of small bowel carcinoma was made preoperatively in 13 cases, based on radiographic data. Surgical resection was the treatment of choice, and this usually involved wide local excision and removal of the involved regional lymph nodes without sacrifice of large portions of the small intestine. Surgical mortality was 11%; one patient died 1 month after a pancreaticoduodenectomy, and a second patient died after biopsy and bypass of unresectable carcinoma in the second part of the duodenum. Awareness of the constellation of symptoms, which are typically insidious and vague early in the course of the disease, should alert the physician to the possibility of small bowel cancer.

6288 NODULAR LYMPHOID HYPERPLASIA OF THE BOWEL IN PRIMARY HYPOGAMMAGLOBULINAEMIA: STUDY OF IN VIVO AND IN VITRO LYMPHOCYTE FUNCTION. (Eng.) Webster, A. D. B.; Kenwright, S.; Ballard, J.; Shiner, M.; Slavin, G.; Levi, A. J.; *et al.* (Northwick Park Hosp. and Clinical Res. Center, Harrow, England). *Gut* 18(5):364-372; 1977.

In vitro and *in vivo* lymphocyte function was studied in six patients with primary hypogammaglobulinemia and nodular lymphoid hyperplasia (NLH) of the bowel. Lymphocyte transformation, numbers of circulating T and B lymphocytes, and delayed hypersensitivity skin tests did not significantly differ when compared with hypogammaglobulinemic patients without NLH. However, patients with NLH had higher jejunal juice IgM concentrations (4-18 IU/ml versus 0-4.5 IU/ml) and a tendency to higher serum IgM concentrations (0-60 IU/ml versus 0-38 IU/ml) than those without NLH. The morphological features of NLH were similar to the germinal center of lymph nodes but more closely resembled the follicle zone of Peyer's patches. These findings suggest that NLH represents a local immune response to antigens originating in the gut lumen.

6289 SECONDARY NEOPLASMS OF THE SMALL BOWEL. (Eng.) Smith, S. J.; Carlson, H. C.; Gisvold, J. J. (Mayo Clinic, Rochester, MN 55901). *Radiology* 125(1):29-33; 1977.

Patterns of proved secondary neoplastic involvement of the small bowel were studied in 33 patients to determine criteria for distinguishing secondary from primary lesions. Secondary neoplasms were distributed throughout the small bowel: 6 in the descending duodenum, 3 in the third portion of the duodenum (all involving the retroperitoneum), 2 in the fourth portion of the duodenum (including the ligament of Treitz), 14 in the jejunum, and 18 in the ileum (including 5 in the terminal ileum). Multiplicity of lesions and the radiologic finding of transverse stretch, i.e., a stretching and fixation of mucosal folds transverse to the longitudinal axis of the bowel lumen, were found to be highly indicative of secondary neoplastic disease. Out of 15 patients exhibiting transverse stretch, with or without intramural involvement, 14 had surgical proof of mesenteric or peritoneal implants. Nodules with deep central ulceration occurred from hematogenous metastasis and were often of a sarcomatous nature. A lesion of the descending duodenum strongly suggested a primary neoplasm in the right colon or right kidney, although local extension from carcinoma of the pancreas could not be ruled out. An example of multiplicity of lesions in the small bowel secondary to involvement from carcinoma of the appendix was shown to include several areas of luminal narrowing, with dilatation of the small bowel proximally, intramural extension as thickened mucosal folds, and, in the right lower quadrant, a large ulcerating tumor mass resulting from direct invasion from the primary site. The most probable route of tumor dissemination to the small bowel in these 33 patients was direct local extension in 17 patients, peritoneal seeding in 13, hematogenous emboli in 6, and noncontiguous extension via fascial or lymphatic pathways in 4. Seven of these patients had evidence of both direct extension and peritoneal seeding.

6290 GASTROINTESTINAL MYOELECTRICAL ACTIVITY IN IDIOPATHIC INTESTINAL PSEUDO-OBSTRUCTION. (Eng.) Sullivan, M. A.; Snape, W. J., Jr.; Matarazzo, S. A.; Petrokubi, R. J.; Jeffries, G.; Cohen, S. (Dept. Medicine, Univ. Pennsylvania, Philadelphia, PA 19104). *N. Engl. J. Med.* 297(5):233-238; 1977.

The myoelectrical and motor function of the esophagus, small intestine, colon, and anal sphincter was evaluated in four patients with chronic idiopathic intestinal pseudo-obstruction. All patients had aperistalsis of the esophagus, with incomplete relaxation of the lower esophageal sphincter after swallowing or balloon distention. Duodenal slow-wave frequency was normal at 11.4 ± 0.3 cycles/min. The patients did not have a normal increase in duodenal spike or motor activity after intestinal distention, but duodenal activity increased after stimulation with i.v. secretin (0.5 U/kg). Colonic slow-wave activities were present at two frequencies, 6.2 ± 0.3 and 3.3 ± 0.1 cycles/min. Neostigmine administration increased both colonic spike and motor activity normally. These studies suggest that in this disorder, physiologic neural responses to swallowing or intestinal distention are impaired, but the intestinal smooth muscle slow-wave activity and the spike and motor responses to exogenous neurohormonal stimulation are intact.

6291 DUODENAL VARICES IN EXTRAHEPATIC PORTAL OBSTRUCTION. (Eng.) Itzchak, Y.; Glickman, M. G. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Radiology* 124(3):619-624; 1977.

Duodenal varices were angiographically demonstrated in 18 patients with extrahepatic portal or splenic vein obstruction. In 11 patients, barium examination of the upper gastrointestinal tract revealed prominent filling defects in the duodenal bulb and the duodenal sweep. Duodenal deformities in these patients were strikingly similar. In 10 of these patients, the deformity was located on the posterior wall of the duodenal bulb and along the greater curvature side of the second portion of the duodenum. Only 1 of the 11 patients showing duodenal deformities had a deformity of the lesser curvature surface of the duodenal bulb or the descending duodenum. The deformities consisted in all cases of sharply margined indentations within the lumen and along the contour of the duodenum and were very similar to the deformities produced in the esophagus by esophageal varices. Demonstration of these deformities should raise the suspicion of extrahepatic portal or splenic vein obstruction, which may be verified by angiography.

6292 FLUID FILLED SMALL BOWEL LOOPS IN GALLSTONE ILEUS: CLINICAL AND EXPERIMENTAL OBSERVATIONS. (Eng.) Bryk, D.; Silverman, M. J.; Venugopal, M. K.; Rind, J.; Levowitz, B. (Jewish Hosp. and Medical Center Brooklyn, 555 Prospect Place, Brooklyn, NY 11238). *Invest. Radiol.* 12(4):357-363; 1977.

A bowel fluid gas index (BFGI) utilizing the proportion of fluid-filled versus gas-filled bowel loops visualized on plain roentgenograms was developed to express the degree of fluid-filled distention in small intestinal obstruction. The BFGI was set up so that in index 1, less than 25% of the visualized loops are fluid filled; in index 2, 25-50% of the loops are fluid filled; in index 3, 50-75% of the loops are fluid filled; and in index 4, more than 75% of the loops are fluid filled. Each of two radiologists made 100 observations on dogs with experimentally produced distal small bowel obstruction, and their average results were 2.34 and 2.38, resp. These results were significant for the means ($p<0.001$) and also for the variances ($p<0.01$). A comparison of BFGI for 55 patients with gallstone ileus and 65 patients with simple adhesive small bowel obstruction gave average BFGI values of 2.9 and 1.9, resp. ($p<0.005$). There was a 33% incidence of index 4 fluid-filled obstruction in cases of gallstone ileus versus only 8% for cases of adhesive obstruction. The BFGI of dogs with experimentally produced distal small bowel obstruction and a cholecystoduodenal fistula operation was 2.8. This was similar to the average BFGI in cases of gallstone ileus and was significantly ($p<0.025$) lower than the BFGI of 1.9 observed in dogs without a fistula and in clinical cases of simple adhesive obstruction.

6293 HEPATIC STRUCTURE AND FUNCTION AFTER MODIFIED JEJUNOILEAL BYPASS SURGERY FOR OBESITY. (Eng.) Maxwell, J. D.; Sanderson, I.; Butler, W. H.; Gazet, J. C.; Pilkington, T. R. E. (St. George's Hosp. Medical Sch., London SW17 0RE, England). *Br. Med. J.* 2(6089):726-729; 1977.

The long-term effects of a modified form of jejunoileal bypass (in which a greater continuous length of ileum is retained) on liver function were examined in 120 patients. Substantial weight loss (119.0 ± 23.3-82.3 ± 18.8 kg) occurred during the first 9 months after surgery, accompanied by a significant rise in serum concentrations of bilirubin, alanine transferase, and alkaline phosphatase, and a significant reduction in albumin concentrations. Biochemical changes were unrelated to weight loss or halothane anaesthesia. After weight stabilization, liver function reverted to normal, and 4 yr after bypass, BSP retention and hepatic histology did not differ from those in obese controls. There were two postoperative deaths. Three other patients died during the period of rapid weight loss with severe hepatic steatosis. While transient mild impairment of liver function is common after modified jejunoileal bypass, clinically significant hepatic dysfunction is a rare and unexplained early complication.

Malabsorption

6308 HEPATIC INJURY IN ADULT COELIAC DISEASE. (Eng.) Hagender, B.; Brandt, L.; Sjolund, K.; Berg, N. O.; Norden, A.; Stenstam, M. (Univ. Hosp., S-221 85 Lund, Sweden). *Lancet* 2(8032):270-272; 1977.

The records of 74 patients with adult celiac disease (ACD) were examined in an attempt to determine the frequency of liver injury in this disease. In 13 cases, histological sections of the liver were available, and in 5 of these there were signs of reactive hepatitis. Histological signs of distinct hepatic injury with cirrhosis and/or chronic active hepatitis were found in seven other patients. In five of these, serum IgA was normal, whereas 16 out of 20 control patients with liver cirrhosis not associated with ACD had raised serum IgA. Serum aspartate aminotransferase and serum alanine aminotransferase were determined in 53 patients; 29 had raised concentrations. In 19 patients, serum aminotransferases were repeatedly determined before and during the dietary regimen, and there was a significant reduction in enzyme concentrations during treatment. The median concentration of serum alkaline phosphatase was also reduced during treatment, but not significantly. The histological evidence of liver injury in 16% and the abnormal liver function tests in 39% of the patients indicate that hepatic injury is common in ACD. Since liver function tests or liver biopsy specimens were available for only about two-thirds of the patients, liver damage in ACD may be more common than indicated by these results. The effect of a gluten-free diet on aminotransferase concentrations indicates that the liver injury may be reversible and suggests that, in some ACD patients, progressive liver damage may be prevented by suitable treatment. Since ACD is not always recognized, the diagnosis should be considered in patients with liver disease of unknown etiology.

6309 ROLE OF BACTERIAL OVERGROWTH IN THE MALABSORPTION SYNDROME OF PRIMARY SMALL INTESTINAL LYMPHOMA IN IRAN. (Eng.) Russell, R. M.; Abadi, P.; Ismail-Beigi, F. (Univ. Maryland, Loch Raven Veterans Admin. Hosp. [151], 3900 Loch Raven Blvd., Baltimore, MD 21218). *Cancer* 39(6):2579-2583; 1977.

Studies were performed on five Iranian patients with primary small intestinal lymphoma to determine the effect of bacterial overgrowth on malabsorption. The effect of oral tetracycline (1.0 g/day) was studied in three patients (1-3). Extensive jejunal resections were carried out at laparotomy in patients 4 and 5. The hemoglobin in three patients (10.0-11.0 g/100 ml) and serum carotenes (15-45 μg/100 ml), serum folate (0.4-8.9 ng/ml), and serum albumin (1.3-3.7 g/100 ml) in all patients were low before the antibiotic treatment. Prothrombin time was abnormal (14.5-19.0 sec) in all subjects, but reverted to normal within 2 days after vitamin K administration. After 1 month of tetracycline therapy, serum carotene (20-70 μg/100 ml), albumin (2.8-3.8 g/100 ml), and cholesterol (121-140 mg/100 ml) rose in all of the treated patients. The results of breath tests for bile salt deconjugation (utilizing glycine-1-^{14}C-cholic acid) were abnormal in all five patients (3.4-11.8 %/mmol $CO_2/10^3$) before the antibiotic treatment. Oral tetracycline had a striking effect towards normalizing the results of breath tests (0.2-2.3 %/mmol $CO_2/10^3$). Schilling tests (with intrinsic factor) improved in two patients (16-40%) and steatorrhea improved in all and there was significant weight gain (3.1-4.6 kg). The antibiotic had no apparent effect on D-xylose or folate absorption tests. It is concluded that bacterial overgrowth in the small intestinal lumen is an important contributory factor to the malabsorption syndrome in primary small intestinal lymphoma.

6310 ALPHA-CHAIN DISEASE AS MALABSORPTION SYNDROME WITH EXUDATIVE ENTEROPATHY.

(Ger.) Roth, S.; Havemann, K.; Kalbfleisch, H.; Menge, H.; Riecken, E. O.; Sodomann, C. P.; Martini, G. A. (Medizinische Universitatsklinik, Mannkopff-str. 1, 3550 Marburg, W. Germany). *Dtsch. Med. Wochenschr.* 101(50):1823-1828; 1976.

The case history of a 30-yr-old man with exudative enteropathy with malabsorption is presented. This case represents the first occurrence of alpha-chain disease, characterized by diffuse proliferations of plasma cells of the IgA system in the area of the small intestine, in West Germany. The patient exhibited three phases of the disease: the first phase showed enteropathy and malabsorption, without improvement following a gluten-free diet; the second phase showed remission with cytostatic therapy using cyclophosphamide and melphalan (combined with steroids); and the third phase showed an increase in the intestinal lymphoma, where melphalan and radiation treatments (2,000 R for entire abdomen and 1,500 R for left para-umbilical region) had only a slight influence on retarding the disease. Diagnosis of small intestinal function indicated a decreased glucose resorption, an increased daily fat excretion, and an increased iron resorption. The upper and middle portions of the small intestine showed hypermotility (under x-ray examination). Histological examination of an extirpated lymph node of the neck revealed a chronic lymphadenitis with sinus catarrh and sinus hystiocytosis. Hematological examination indicated a hypochromic anemia of the peripheral blood and hypoproteinemia. There were granuloma-like proliferations in the liver and lymphoid elements in the marrow. Atrophy of the villi of the small intestine and plasma-cellular infiltrations of the lamina propria (jejunum and ileum) were also evident. Following surgery to remove a conglomerate tumor and enlarged lymph nodes from the mesenterial root, the patient's condition deteriorated, eventually leading to his death.

6311 STEATORRHOEA IN THE ELDERLY. (Eng.)

Price, H. L.; Gazzard, B. G.; Dawson, A. M. (St. Bartholomew's Hosp., London EC1A 7BE, England). *Br. Med. J.* 1(6076):1582-1584; 1977.

To assess the etiology and the clinical and laboratory features of steatorrhea in the elderly, experience with 47 patients who presented with this entity after the age of 50 yr was analyzed. The causes of steatorrhea were celiac disease (16), pancreatic insufficiency (10), pancreatic carcinoma (4), postgastrectomy steatorrhea (8), jejunal diverticula (2), tropical sprue (2), collagen disease (1), diabetes mellitus (1), scleroderma (1), and Whipple's disease (1); the cause of steatorrhea was undetermined in one patient. The most common cause of steatorrhea was celiac disease in patients under 65 yr and pancreatic insufficiency in those over 65. Pancreatic insufficiency was the most common cause of steatorrhea in men (9/30), whereas celiac disease was the most common cause in women (10/17). Half the patients with celiac disease had a hemoglobin concentration of less than 10 g/dl, while patients with pancreatic insufficiency all had values above this level. Serum xylose concentrations after a xylose test meal were decreased in six of nine celiac patients tested, but in none of the four patients with pancreatic insufficiency. The glucose tolerance test result was diabetic in 9 of 12 patients with pancreatic insufficiency but was normal or flat in 8 of 9 patients with celiac disease and 9 of 10 patients with other causes of steatorrhea. Barium examination of the small bowel was mainly useful in showing jejunal diverticula but also showed a malabsorption pattern in 13 of 16 patients with celiac disease and 2 with pancreatic insufficiency. The ESR and serum albumin concentration were not helpful in determining the cause of steatorrhea. A jejunal biopsy and Lundh test, together with a barium follow-through to exclude small bowel diverticula, are helpful in establishing the correct cause of steatorrhea in most elderly patients.

6312 ETIOPATHOGENETIC STUDIES IN A PATIENT WITH WHIPPLE'S DISEASE. (Eng.)

Tytgat, G. N.; Hoogendijk, J. L.; Agenant, D.; Schellekens, P. Th. (Dept. Medicine, Univ. Amsterdam, Amsterdam, Netherlands). *Digestion* 15(4):309-321; 1977.

A case report is presented of a patient having Whipple's disease (hospitalized for marked weakness, dyspnea, fatigue, anorexia, epigastric pain, and intermittent attacks of shortness of breath). Characterization of the invading microorganism and of the immunological disturbances was attempted. Gross distortion of the villus architecture due to massive accumulation of PAS-positive macrophages and large lipid-filled cystic spaces in the lamina propria occurred. Abnormal values were reported for serum calcium (1.93 mmol/l), d-xylose excretion (21 instead of >33 mmol/5 hr), and fecal fat (17 instead of <6 g/day). X-ray examination revealed coarsening of the fold pattern with superimposed nodular indentations. Before treatment, *Haemophilus influenzae* type e, sensitive to tetracycline, was cultured from multiple small intestinal biopsies. This isolated microorganism was structurally similar to one observed in the tissue. All further culture experiments during and after treatment (tetracycline, 2-3 g/day) proved negative except for one biopsy from which a tetracycline-resistant *H. influenzae* type-e mutant was isolated. The immunological disturbances, mainly characterized by cutaneous anergy, in the absence of major humoral or *in vitro* lymphocytic impairment, regressed during treatment together with clinical remission of the disease. The patient recovered and no recurrence of the disease occurred until his death (2.5 yr after recovery) due to massive stroke. It is suggested that the immunological disturbances are of a secondary nature in this disease.

6313 BILATERAL COXARTHROSIS REVEALING WHIPPLE'S DISEASE: CASE REPORT. (Fre.) Le Chevallier, P.; Vallat, J. P.; Luthier, F.; Methan, E.; Janvoie, L.; Medelsi, M. (Centre Hospitalier Regional Bretonneau, F 37033 Tours Cedex, France). *Rev. Rhum. Mal. Osteoartic.* 43(11):663-668; 1976.

See also, 6043, 6162, 6163, 6167, 6263, 6288, 6303, 6586, 6595, 6596, 6606, 6609, 6610.

6322 ARTERIOVENOUS MALFORMATIONS OF THE COLON. (Eng.) Hagihara, P. F.; Chuang, V. P.; Griffen, W. O. (Dept. Surgery, Univ. Kentucky Coll. Medicine, Lexington, KY 40506). *Am. J. Surg.* 133 (6):681-687; 1977.

The case reports of four patients (a 60-yr-old man and 3 women, 72, 43, and 50 yr old) in whom arteriovenous malformations were recognized as the major cause of massive rectal bleeding of colonic origin are discussed. Selective mesenteric angiography was used to correctly diagnose the site of vascular malformations in these patients and hemicolectomy or colostomy was performed after the diagnosis. Although an arteriographic unit capable of serial magnification was ideal for detecting arteriovenous malformations in the bowel, the diagnosis may be made by a combined approach of conventional arteriography, colonoscopy, laparotomy, and operative judgement. The final diagnosis and proof of correct surgical extirpation rests on gross and histologic demonstration of vascular malformations in the excised specimen.

6323 BREATH-METHANE IN PATIENTS WITH CANCER OF THE LARGE BOWEL. (Eng.) Haines, A.; Dilawari, J.; Metz, G.; Blendis, L.; Wiggins, H. (Northwick Park Hosp., Watford Rd., Harrow, Middlesex HA1 3UJ, England). *Lancet* 2(8036):481-483; 1977.

The breath methane levels were compared in 30 patients with carcinoma of the rectum or colon, 64 patients with nonmalignant large bowel disease, and 208 subjects without large bowel disease. Eighty percent of the patients with large bowel cancer had detectable levels of methane (i.e., 1 ppm above the methane content of room air, which is usually 2-3 ppm) in their breath, compared with 39% of the patients with nonmalignant large bowel disease and 40% of subjects without disease. These findings suggest that there may be a difference in anaerobic intestinal bacteria between patients with large bowel cancer and those without the disease.

6324 BOWEL TRANSIT-TIME AND STOOL WEIGHT IN POPULATIONS WITH DIFFERENT COLON-CANCER RISKS. (Eng.) Glober, G. A.; Kamiyama, S.; Nomura, A.; Shimada, A.; Abba, B. C. (Kuakini Medical Center, 347 N. Kuakini St., Honolulu, HI 96817). *Lancet* 2(8029):110-111; 1977.

Bowel transit time was studied in 25 Caucasians living in Hawaii, 67 Japanese living in Hawaii, and 28 Japanese living in Japan to determine why the incidence rate for colon cancer in the two groups living in Hawaii is higher than that for the Japanese living in Japan. The mean bowel transit times in Caucasians, Japanese from Hawaii, and Japanese from Japan were 56.2, 31.4, and 33.9 hr, resp.; thus, the transit times in the two Japanese groups were similar ($p=0.47$), and the transit time in the Caucasians was significantly higher than that in both the Hawaiian Japanese ($p<0.001$) and in the Japanese from Japan ($p<0.005$). The Japanese in Japan had significantly heavier stool specimens (194.7 g) than did the Caucasians (119.7 g, $p<0.01$) and the Japanese living in Hawaii (120.7 g, $p<0.001$). The mean interval between bowel movements was similar in the three groups. Correlation between bowel transit time and estimated weekly consumption of 33 different food items was investigated; the foods included beef, bacon, celery, tomatoes, lettuce, milk, rice, noodles, and green tea. No food correlated with bowel transit time in the three groups. Stool weight may be indirectly related to the risk of colorectal cancer, polyposis, or diverticulosis in the Japanese.

6325 THE DIAGNOSTIC PATTERN OF DNA-CONTENT IN THE "BORDERLINE" NEOPLASM OF THE LARGE INTESTINE. (Eng.) Shindo, K. (Dept. Surgery, Osaka Univ. Hosp., Osaka 553, Japan). *Am. J. Proctol.* 28(4):57-64; 1977.

Microspectrophotometric measurements of DNA content were done in normal, benign, "borderline" (atypical neoplasm--neither benign nor malignant), and malignant epithelial cells of the large intestine of man (30 specimens) and rat (42 specimens). The distribution of the DNA values was very narrow in normal mucosa (less than 1.5 n, a near diploid value), narrow in benign lesions (less than 2.2 n, the hyperdiploid range), and broad in malignant lesions (more than 4.2 n, the hypotriploid range). The rate of number of nuclei greater than the tetraploid value (4.0 n) was null in normal, less than 5.3% in benign, and more than 6.7% in malignant cells. This method was found useful for diagnostic means or for evaluation of the prognosis in the borderline lesions. The borderline lesions could be designated malignant if the mean DNA value is >2.5 n, the nucleus over 4 n is >6%, and the width of distribution is >2.8 n. It is suggested that these criteria may be applied to the experimental animal to determine the presence of malignancy.

6326 THE EARLY DETECTION OF COLORECTAL CANCER. (Eng.) Miller, S. F.; Knight, A. R. (Miami Valley Hosp., 1 Wyoming St., Dayton, OH 45409) *Cancer* 40(1):945-949; 1977.

The results of a screening program for the early detection of colorectal cancer are presented. Among 2,332 individuals screened, 2 of 28 with rectal masses (detected by rectal examination) and 1 of 11 with positive Hemoccult slides on two sets of testing were found to have early colorectal carcinoma. Rectal examination revealed two individuals with carcinoma of the rectum (one a Dukes' A and the other a Dukes' B), and a barium enema examination revealed one case of Dukes' B carcinoma of the rectosigmoid colon. Although both proctosigmoidoscopy and guaiac impregnated filter slide paper methods have been productive in the early diagnosis of colorectal cancer, the Hemoccult test is inexpensive, can be used on a routine basis, is easier for patients to perform themselves, and represents a significant cost savings over proctosigmoidoscopy. It is recommended that the Hemoccult test be routinely used in all patients over 40 yr of age. Patients who have persistently positive Hemoccult tests after diet therapy should be submitted to proctosigmoidoscopy and barium enema examination.

6327 MUCIN PRODUCING CARCINOID TUMOURS OF THE VERMIFORM APPENDIX. (Eng.) Haqqani, M. T.; Williams, G. (Dept. Pathology, Stopford Building, The Univ., Manchester M13 9PT, England). *J. Clin. Pathol.* 30(5):473-480; 1977.

Six cases of an unusual mucoid variant of carcinoid tumor of the appendix are reported. These lesions are small, detected incidentally, and carry a good prognosis. All tumors had similar histological appearances of well-differentiated microacini and cellular rosettes infiltrating the base of the mucosal glands or the deeper muscle layers in four cases and as far as the serosa in two cases. The dominant picture was that of cellular rosettes and clusters lacking a central lumen; the cytoplasm was distended with mucin, giving a vacuolated appearance. Nuclei were basal, small, ovoid, and regular with delicate nuclear membranes and finely dispersed chromatin. There was no pleomorphism or cellular atypia. Paneth cells were usually present and an invasion without necrosis was reported. Appreciable numbers of argentaffin and argyrophil cells were reported in mucinous carcinoids. These tumors showed distinct differences from ordinary carcinoid tumors and adenocarcinoma, even though the mucin secreted by goblet cells of the normal mucosal epithelium and by the cells of these carcinoid tumors showed similar histochemical similarities (Alcian blue binding occurred in 0.2-0.6 M concentration of electrolyte). It is suggested that appendectomy is curative and right hemicolectomy is unnecessary unless the base of the appendix or adjacent cecum is invaded.

6328 ISCHEMIC COLITIS ASSOCIATED WITH CARCINOMA OF THE COLON. (Eng.) Whitehouse, G. H.; Watt, J. (Univ. Liverpool, Nuffield Unit Medical Genetics, Crown St., Liverpool L69 3BX, England). *Gastrointest. Radiol.* 2(1):31-35; 1977.

wo cases of ischemic colitis occurring proximal to arcinoma of the colon are described, with special eference to the barium enema and pathological findngs. The first patient, a 52-yr-old man, presented ith lower abdominal pain and rectal bleeding. The arium enema examination revealed typical changes f colitis with "thumb printing" proximal to a neolasm of the transverse colon. In the second paient, a 67-yr-old man, the presenting features ere those of a lower colonic obstruction without ectal bleeding, and the radiological examination evealed a smooth and obviously benign stricture roximal to a stenosing carcinoma of the descending olon. In both cases, the gross pathology and the icroscopic changes in the bowel proximal to the umor were consistent with those of ischemic coltis in a subacute or chronic phase. The ischemic rigin of the mucosal ulceration and other changes that occur proximal to obstructive colonic neoplasms may be initially suspected on the basis of the clinical presentation. Ischemia of the bowel wall in these cases, and particularly where the transverse colon is involved (as in the first patient), may not be dependent upon defects in arterial anastomoses as in "ischemic colitis" occurring in the absence of an obstructive lesion.

6329 ANTIBIOTIC-ASSOCIATED COLITIS. (Eng.) Miller, R. R.; Jick, H. (Boston Collaborative Drug Surveillance Program, 400 Totten Pond Rd., Waltham, MA 02154). *Clin. Pharmacol. Ther.* 22(1):1-6; 1977.

Data on 26,294 patients hospitalized since 1966 were examined to provide some index of the frequency of antibiotic-induced colitis. Among the 26,294 patients, 8,948 received at least one antibiotic (ampicillin, 3,988; chloramphenicol, 437; lincomycin, 90; clindamycin, 163; tetracycline, 1,517). None of these patients were diagnosed as having drug-induced colitis due to in-hospital antibiotic exposure. However, seven patients who had taken antibiotics as outpatients were admitted with antibiotic-associated colitis. Six patients had taken lincomycin, and one had taken ampicillin. Six patients were hospitalized in New Zealand and one in Canada. The five patients with lincomycin-associated colitis at the New Zealand hospital were admitted over an 11-month period. Severe colitis due to antibiotics has been a rare event, especially in the United States.

6330 COLONIC ILEUS. (Eng.) Meyers, M. A. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *Gastrointest. Radiol.* 2(1):37-40; 1977.

Nine cases of colonic ileus, characterized by selective or disproportionate distention of the large intestine without organic obstruction, are summarized. The patients ranged in age from 33 to 80 yr, and all patients had a prior systemic abnormality or had undergone a pelvic operation (acute myelocytic leukemia, lymphosarcoma, hip nailing, total abdominal hysterectomy, appendectomy, suprapubic prostatectomy, lumbar laminectomy, and Caesarian section). The clinical picture was similar to that of mechanical colonic obstruction; progressive abdominal distention became apparent in 2-7 days in those patients who underwent surgery, although the passage of liquid feces and gas did occur. Abdominal radiographs demonstrated striking dilatation of the colon with gas; this was present to the hepatic flexure in one case, to the splenic flexure in six cases, to the distal descending colon in one case, and to the mid-descending colon in one case. Massive distention of the cecum dominated the radiographic presentation, and the cecal diameter ranged between 8.5 and 18 cm. Minimal small bowel dilatation was present in two patients. The symptoms resolved with conservative therapy in six patients. Cecostomy was necessary to prevent peritonitis in two patients, and the remaining patient died from cecal perforation. The clinical importance of this type of colonic ileus lies in its distinction from true mechanical obstruction and in the fact that it can progress to perforation.

6331 NONISCHEMIC INTUSSUSCEPTION. (Eng.) Janik, J. S. (Cook County Hosp., 1825 W. Harrison, Chicago, IL 60612). *J. Pediatr. Surg.* 12(4):567-570; 1977.

The symptoms, diagnosis, and therapy of 20 children with nonischemic intussusception are reported. These children were among 123 patients treated for intussusception at one hospital during a 1-yr period. Unlike patients with acute intussusception, these children exhibited signs of incomplete bowel obstruction, no intestinal ischemia, and a longer duration of symptoms (usually 4-14 days). Approximately 50% of the 20 children did not demonstrate rectal bleeding or a palpable abdominal mass. The incidence of diarrhea among these patients (45%) was three times that in patients with acute intussusception. The incidence of specific lead point pathology among the children with nonischemic intussusception (25%) was twice that in patients with acute intussusception. The correct diagnosis was made on admission in only 45% of the patients with nonischemic intussusception, whereas this incidence was 70% in the children with acute intussusception. Most often, the diagnosis of gastroenteritis was made instead. Of the 20 children, barium hydrostatic reduction was attempted in 12. Six of these intussusceptions were successfully reduced, but three of these reductions were not recognized until laparotomy was carried out. The intussusception was manually reduced at surgery in 11 cases, and resection was required in the remaining three patients. Pathologic examination did not demonstrate gangrene in any case. Meckel's diverticulectomy was performed in four children. No morbidity, mortality, or recurrence was recorded following therapy in any of the 20 patients. Despite the longer duration of symptoms in nonischemic intussusception, it can be treated initially with a careful attempt at barium hydrostatic reduction. If this fails, easy operative manual reduction is possible.

6332 WHEAT FIBRE AND IRRITABLE BOWEL SYNDROME: A CONTROLLED TRIAL. (Eng.) Manning, A. P.; Heaton, K. W.; Harvey, R. F.; Uglow, P. (Duke Univ. Medical Center, Durham, NC). *Lancet* 2(8035):417-418; 1977.

A controlled trial was carried out in 26 patients with the irritable bowel syndrome to determine the effect of a high- or low-fiber diet. After 6 weeks on a high wheat fiber regimen (adding 5.6-6.6 g of wheat fiber to the existing diet of 60 ml fine unprocessed wheat bran), the frequency of pain was significantly reduced ($p<0.05$); this did not occur in the patients on the low-fiber diet. The patients on the high-fiber diet also showed a significant decrease in the pain-severity score ($p \approx 0.01$), whereas those on the low fiber diet did not. On the high-fiber diet, bowel habit was improved in seven patients, unchanged in six, and worse in none. On the low fiber diet, two patients improved, five were unchanged, and four became worse; this difference in response to the diets was significant ($p<0.05$). Colonic motor activity was significantly reduced on the high-fiber diet ($p<0.01$) but was unchanged on the low-fiber diet. Patients with the irritable bowel syndrome should be encouraged to increase their daily intake of wheat fiber.

6333 THE CLINICAL SIGNIFICANCE OF PNEUMATOSIS CYSTOIDES INTESTINALIS: A REPORT OF 5 CASES. (Eng.) Thomson, W. O.; Gillespie, G.; Blumgart, L. H. (Royal Infirmary, Glasgow, Scotland). *Br. J. Surg.* 64(8):590-592; 1977.

The cases of five patients with pneumatosis cystoides intestinalis are presented. The patients ranged in age from 41 to 72 yr (2 women, 3 men). Chronic bronchitis was present in three patients. The symptoms included abdominal pain, flatulence, constipation, diarrhea, rectal bleeding, and mucous discharge per rectum. In one patient, the results of a barium enema examination were thought to indicate gross polyposis, and an unnecessary colectomy with ileorectal anastomosis was carried out; in another patient, polyposis was misdiagnosed at sigmoidoscopy, and laparotomy was only avoided when a radiological review indicated the presence of pneumatosis. This patient and another responded to conservative treatment. Chest x-ray in one patient revealed a massive amount of free gas under the diaphragm, with downward displacement of the liver and interposition of loops of bowel between the liver and diaphragm (Chilaiditi's sign). Although intestinal gas cysts were not visualized, the presence of a chronic asymptomatic pneumoperitoneum together with this sign suggested pneumatosis. A fifth patient had pneumatosis in association with a small bowel fistula, multiple abdominal adhesions, and intermittent obstructive episodes, eventually necessitating a colostomy. These cases illustrate the variety of presentations of pneumatosis cystoides intestinalis. Good results can be achieved in most cases by conservative means.

6334 THE EPIDEMIOLOGY OF COLORECTAL POLYPS: PREVALENCE IN NEW ORLEANS AND INTERNATIONAL COMPARISONS. (Eng.) Correa, P.; Strong, J. P.; Reif, A.; Johnson, W. D. (Dept. Pathology, Louisiana State Univ. Medical Center, 1542 Tulane Ave., New Orleans, LA 70112). *Cancer* 39(5):2258-2264; 1977.

The prevalence of colorectal polyps in New Orleans is reported and compared with data on this disease from other geographic locations to explore the epidemiological aspects of the polyp-cancer relationship. A close parallelism in the epidemiology of colon cancer and adenomatous polyps (proliferations of intestinal epithelial cells arranged in tubular fashion) is noted. Both conditions are statistically associated with respect to geography (in men, 63% prevalence of polyps--very high frequency of colon cancer in Hawaii-Japanese population; 37% prevalence of polyps--high frequency of colon cancer in New Orleans population), anatomic localization (17.5% of polyps were located between 10 and 22 cm from the anorectal junction in the New Orleans population, which is comparable to the 1.7 times excess of cancer in the sigmoid area in this population when compared to other populations), socio-economic class, migration experience (the Japanese and South African blacks have low rates in their home countries but have high incidence after migration), and time trends (age adjusted prevalence increased from 17 men in St. Louis, MO in 1947 to 63 men in Honolulu, HI in 1972). The size (average 6.5 mm) and prevalence of adenomatous polyps increased with age in the New Orleans population. The association favors the notion of direct, positive correlation between multiplicity, size, and atypia of polyps and cancer risk. The epidemiologic findings are coherent with other biologic facts derived from clinical, morphological, and experimental studies. Adenomatous polyps are a good epidemiologic indicator of colon cancer risk, and their presence should be helpful in studying the epidemiology of precursor lesions of colon cancer.

6335 SYPHILITIC PROCTITIS. (Eng.) Akdamar, K.; Martin, R. J.; Ichinose, H. (Tulane Univ. Sch. Medicine, Tulane Ave., New Orleans. LA 70112). *Am. J. Dig. Dis.* 22(8):701-704; 1977.

The cases of two male homosexuals with syphilitic proctitis are presented. One patient presented with symptoms similar to those reported previously: lower abdominal pain, blood-streaked stool, tenesmus, and rectal bleeding. A generalized macrulopapular skin rash was present. Proctoscopy revealed tender fibrotic-appearing lesions on the anterior and posterior rectal wall at 2, 7, and 9 cm. Biopsy showed an inflammatory vasculitis, and Warthin-Starry silver stain demonstrated many spirochetes. The patient's liver function test was abnormal, SGOT being 225 mU/ml, and the alkaline phosphatase being 170 mU/ml. The other patient was unusual in that there was no rectal pain and diffuse involvement of the rectum up to 20 cm was present. He had a 5-month history of abdominal discomfort associated with excessive mucoid diarrhea. Severe rectal bleeding occurred following biopsy. The biopsy material revealed a mixed lymphocytic and histiocytic vasculitis with reactive submucosal granulation tissue. Spirochetes were not demonstrated by the Warthin-Starry silver-stained sections. The patient experienced a Jarisch-Herxheimer reaction following the first injection of penicillin. There was no history or evidence of an external primary chancre in either patient, and both responded to penicillin therapy.

6336 VOLVULUS OF THE TRANSVERSE COLON. (Eng.) Eisenstat, T. E.; Raneri, A. J.; Mason, G. R. (Univ. Maryland Hosp., Baltimore, MD 21201). *Am. J. Surg.* 134(3):396-399; 1977.

The case reports of five patients with volvulus of the transverse colon are presented. Two patients had acute volvulus, the presentation being characterized by early obstruction of the mesenteric vessels. The other three patients presented with chronic volvulus, which was characterized by a gradual onset of symptoms, with periods of spontaneous decompression and exacerbations, painless abdominal distention, and an infrequent history of vomiting. A barium enema examination was carried out in three patients, two of which revealed obstruction at the splenic flexure. No reductions of the volvulus were accomplished by the enema. The diagnosis of volvulus of the transverse colon was not made preoperatively in any patient. Among the patients with chronic volvulus, one underwent resection with colostomy and mucous fistula, one underwent cecostomy only, and one underwent primary anastomosis with no fecal diversion; all patients recovered. Preparation of the patients with acute volvulus for surgery required aggressive fluid replacement and correction of severe acid-base imbalances. The course of one patient with acute volvulus was complicated by respiratory compromise secondary to dilated intestine and elevated diaphragm. A gangrenous transverse colon was found at laparotomy. Resection with colostomy and mucous fistula were carried out in both patients. Two of the five patients had had previous operations for colonic volvulus. The level of volvulus dictates the limitations of diagnostic aides and appropriate treatment.

6337 CECAL CHANGES FOLLOWING APPENDECTOMY. (Eng.) Ekberg, O. (Malmo General Hosp., S-21401 Malmo, Sweden). *Gastrointest. Radiol.* 2(1):57-60; 1977.

The appearance of the cecum was followed from 2 days to 18 months after appendectomy in 12 patients. All patients had histologically normal appendices but had signs of terminal ileitis *(Yersinia enterocolitica)* with edematous and hyperemic serosa together with enlarged lymph nodes. The appendix was removed, and the stump was invaginated twice in all cases. Radiologic examination of the ileocecal area was carried out on a total of 31 occasions during the 18-month period, and each patient had at least two examinations. Four kinds of cecal changes were seen: general deformation of the whole cecum, localized deformation of the medial aspect of the cecum, combination of a localized deformation with a general deformation of the whole cecum, and normal cecum. General deformation of the cecum or general deformation together with medial deformation occurred in five patients. Five of seven patients examined within 2 weeks after surgery had the localized deformation, and two were normal. Seven of the 11 patients examined within 6 weeks of surgery had the localized deformation, and 4 were normal. This condition disappeared within 18 months in four of the eight patients in whom it was present at one time or other. The localized defect was consistent in size and measured an average of 2 x 2 cm.

6348 BILE ACIDS IN LIVER DISEASE ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE. (Eng.) Siegel, J. H.; Morris, J. S. (Royal Free Hosp., London, England). *Digestion* 15(6):469-481; 1977.

Bile acids in portal blood and gallbladder bile were studied in 9 patients with chronic bowel disease alone, 13 patients with bowel disease (ulcerative colitis) and liver disease, 10 patients with chronic liver disease alone, and 14 control patients to investigate the possibility that bowel-related liver disease is due to accumulation of abnormal bile acids in the enterohepatic circulation. There was no difference in the composition and concentration of bile acids (cholic, chenic, deoxycholic, and lithocholic acids) in bile and portal blood of patients without clinical liver disease compared with the control patients. Lithocholic acid was detected in small concentration (<1 μM). Bile acid concentrations and composition were similar in the two groups of patients with liver disease, whether they had bowel disease or not. Lithocholic acid was found in concentrations of up to 1.5-1.8 μM in 6 of 13 patients with liver disease. Postprandial serum bile acid concentrations were not elevated in the group of patients with chronic bowel disease, suggesting normal liver function in this group. No evidence was reported to support the hypothesis that bowel-related liver disease in man results from the action of abnormal bile acids.

6349 IMMUNOHISTOCHEMICAL AND ELECTRONMICROSCOPIC OBSERVATIONS ON THE LOCAL IMMUNE RESPONSE IN ULCERATIVE COLITIS.

(Eng.) Gebbers, J. O.; Otto, H. F. (Pathologisches Institut der Universitat, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 374(4): 271-273; 1977.

Colonoscopically obtained biopsy specimens of 50 young patients with ulcerative colitis were examined for the presence and distribution of immunoglobulin-containing cells by the indirect immunoperoxidase method and by electron microscopy. The numbers of plasma cells and of IgG-containing cells were increased, and there was a relative decrease in IgA cells. The IgM and IgE cell populations were not altered quantitatively. Free interstitial IgG was demonstrated in the lamina propria, and this was bound to the basement membrane of the surface epithelium. Complement was observed at this site and was also found in the intercellular space of the surface epithelium. This latter finding was seen only in cases of acute relapse of the disease. Russell bodies and Mott cells were seen within the plasma cells. There were numerous necrobiotic plasma cells, explaining the deposits of interstitial immunoglobulin. Close topographical relationships of lymphocytes and macrophages were observed, and both cell types appeared to be activated. Lymphocytes and plasma cells were clustered around activated macrophages, which may be the morphological expression of a functional involvement of macrophages in the local B-cell response. The findings support the suggestion that immune complexes occur locally in ulcerative colitis and play a part in the pathogenesis of this disease.

6350 IMMUNE COMPLEXES IN ULCERATIVE COLITIS AND CROHN'S DISEASE.

(Eng.) Hodgson, H. J. F.; Potter, B. J.; Jewell, D. P. (Royal Free Hosp., London NW3, England). *Clin. Exp. Immunol.* 29(2):187-196; 1977.

Sera from 156 patients with ulcerative colitis (UC) and Crohn's disease (CD) and from controls (normal subjects and hospital in-patients with diseases believed not to affect their immunological status) were tested for the presence of immune complexes by the detection of anti-complementary activity and ^{125}I-labeled Clq precipitation. Using aggregated IgG, a comparison between the two tests indicated that the anti-complementary test was the most sensitive to aggregates of 11S in size, while the ^{125}I-labeled Clq test detected aggregates over 20S in size. The correlation coefficient between the two tests was 0.2060 ($p<0.01$). Anti-complementary activity in excess of 1.90 CH_{50} units was seen in 29 of 90 patients with ulcerative colitis and 17 of 64 patients with Crohn's disease (both accompanied and not accompanied by extra-intestinal manifestations such as acute and chronic arthritis, ankylosing spondylitis, and liver disease). Large complexes were common only in patients with liver disease. When patients with extra-intestinal manifestations were excluded, a higher proportion of patients with moderate or severe disease showed excess anti-complementary activity, compared with patients with mild disease or in remission (CD, $p<0.05$; UC, $p<0.1$). The mean anti-complementary activity of 18 patients in remission fell as their clinical state improved ($p<0.001$). The immunoglobulin levels showed no such consistent changes. It is suggested that immune complexes in the gut mucosa play a role in the pathogenesis of these diseases, and that the deposition of circulatory immune complexes may explain at least some of the extra-intestinal manifestations.

6351 ULCERATIVE COLITIS IN A PATIENT WITH ANTI-B LYMPHOCYTOTOXIN AND HYPOGAMMAGLOBULINEMIA.

(Eng.) Matuchansky, C.; Messing, B.; Tursz, T.; Galian, A.; Bernier, J. J.; Seligmann, M.; *et al.* (Hotel-Dieu, 86021 Poitiers, France). *Gastroenterology* 73(3):578-582; 1977.

The case of a 32-yr-old woman with chronic ulcerative colitis, primary hypogammaglobulinemia and a very low number (0.5-1.5%) of bone marrow-derived (B) lymphocytes in peripheral blood is described. A lymphocytotoxin (LCT) reacting specifically with B cells was demonstrated in the serum by cytotoxicity and direct immunofluorescence experiments. Intestinal immunofluorescence studies indicated a dichotomy between blood and gut immunoglobulins, and showed a heterogeneous distribution of plasma cells of the three major classes from the jejunum to the rectum. The dissociation between blood and gut immunoglobulins may have been due to the fact that the intestine was, in this patient, a privileged site for differentiation of B cells.

6352 COLECTOMY AND ILEORECTAL ANASTOMOSIS FOR COLITIS: REPORT ON A PERSONAL SERIES, WITH A CRITICAL REVIEW.

(Eng.) Jones, P. F.; Munro, A.; Ewen, S. W. B. (Woodend General Hosp., Aberdeen, AB9 2YS, Scotland). *Br. J. Surg.* 64(9):615-623; 1977.

In a consecutive series of 86 patients who required total colectomy for inflammatory bowel disease, 36 had an ileorectal anastomosis. On review between 1 and 18 years after the operation, there were 25 patients who retained the anastomosis, all of whom were in good general health. Bowel obstruction (3 patients) and lung and pelvic abscess (1 patient) were the major problems encountered after the operation. Five patients died of various causes after surviving for 5 months to 14 year. Four patients required laparotomy for adhesive intestinal obstruction at a late stage. One patient who had ankylosing spondylitis before operation was reported to have symptoms intermittently, and another patient developed arthritis. Of the 25 survivors, 23 had had ulcerative colitis (UC) and 2 had had Crohn's disease. All 23 patients with UC lead a normal life. The frequency of bowel movement is 3-6 stools daily. No evidence of precancer in the biopsies of the rectal stumps of 22 patients was reported. Only nine of the patients have been on sulphasalazine continuously. The results are compared with other published reports in a critical review of the present standing of ileorectal anastomosis. Ileorectal anastomosis is a good operation for suitable patients, but, due to risk of development of carcinoma of the rectum in patients with UC, it is suggested that patients be available for and willing to undergo annual sigmoidoscopic examination.

6353 ULCERATIVE COLITIS AND CROHN'S COLITIS: DIFFERENTIAL DIAGNOSIS AND TREATMENT. (Eng.) Northfield, T. C. (St. George's Hosp. Medical Sch., Cranmer Terrace, London SW 17 ORE, England). *Drugs* 14(3):198-206; 1977.

PANCREAS

6358 AMYLASE THERMOLABILITY IN BODY FLUIDS. (Eng.) Donaldson, L. A.; McIntosh, W. B.; Brodie, M. J. (Stobhill General Hosp., Glasgow, Scotland). *Scand. J. Gastroenterol.* 12(5):637-639; 1977.

In an attempt to differentiate the isoenzymes of human amylase, the thermolability of amylase was measured in saliva, pancreatic juice, urine, and adult and neonatal sera. Amylase activity was estimated before and after heating the test fluids at 65 ± 0.5 C for 15 min. The mean percentage thermolability from these fluids was 100%, 99%, 87%, 44%, and 23%, resp. In patients with acute pancreatitis and mumps, the amylase was 84% and 83% thermolabile during the acute phase. On resolution of the pancreatitis, this dropped towards normal. Patients with a pancreatic pseudocyst showed a high mean percentage thermolability (82%). These results suggest that a component of amylase in human serum is not of pancreatic or salivary origin. In addition, this simple technique may be helpful in the diagnosis of pancreatic pseudocyst.

6359 SONOGRAPHIC DIAGNOSIS OF PANCREATIC DISEASES. (Eng.) Lutz, H. T. (Dept. Medicine, Univ. Erlangen-Nurnberg, D-8520 Erlangen, W. Germany). *Ultrasound Med. Biol.* 3(1):55-57; 1977.

The diagnostic accuracy of ultrasonography was compared with that of endoscopic retrograde pancreatography (ERP) in 316 patients. Among 130 patients with pancreatitis, 48 with pseudocyst, 37 with carcinoma, and 101 with a normal pancreas, ultrasound was not possible in 6.7%, provided a borderline diagnosis in 8.5%, was false-negative in 1.9%, was false-positive in 5.4%, and indicated the correct diagnosis in 77.5%. In the same patients, ERP was not possible in 14.9%, was false-negative in 3.8%, was false-positive in 0.6%, and indicated the correct diagnosis in 80.7%. Among the 191 patients in whom ultrasonography indicated some type of pancreatic disease, the differential diagnosis was further aided by this procedure in 138. The results indicate that ultrasonography is the safest and least expensive diagnostic method in pancreatic diseases.

6360 TREATMENT OF ADVANCED ADENOCARCINOMA OF THE PANCREAS WITH COMBINATIONS OF STREPTOZOTOCIN PLUS 5-FLUOROURACIL AND STREPTOZOTOCIN PLUS CYCLOPHOSPHAMIDE. (Eng.) Moertel, C. G.; Douglas, H. O., Jr.; Hanley, J.; Carbone, P. P. (Mayo Clinic, Rochester, MN). *Cancer* 40(2):605-608; 1977.

Combination chemotherapy with streptozotocin and 5-fluorouracil or combined streptozotocin and cyclophosphamide were compared in 116 patients with advanced and metastatic pancreatic adenocarcinoma. Toxic reactions to each regimen were qualitatively similar and consisted of nausea and vomiting during treatment and subsequent leukopenia and thrombocytopenia. Renal toxicity was less frequent and only rarely severe. Among 51 eligible and evaluable patients treated with the streptozotocin-cyclophosphamide combination, 12% showed objective response and among 42 patients treated with streptozotocin plus 5-fluorouracil, 12% showed objective response. The streptozotocin plus 5-fluorouracil-treated patients showed a slight advantage in survival. Neither regimen can be considered of substantive value to the patient with advanced pancreatic carcinoma.

6361 PERCUTANEOUS FINE NEEDLE ASPIRATION BIOPSY OF PANCREATIC CARCINOMA. (Eng.) Clouse, M. E.; Gregg, J. A.; McDonald, D. G.; Legg, M. A. (New England Deaconess Hosp., 185 Pilgrim Rd., Boston, MA 02215). *Gastrointest. Radiol.* 2(1):67-69; 1977.

The use of percutaneous fine needle aspiration biopsy in the diagnosis of pancreatic carcinoma was evaluated in 13 patients with carcinoma. The tumor was localized by angiography in eight, ultrasound in five, and endoscopic retrograde pancreatography in three patients. In four patients aspiration was performed using two of the three localizing techniques. Tumor cells were aspirated in six of the eight patients in whom angiography was used to localize the tumor. Positive aspirates were obtained in two of three patients using endoscopic retrograde pancreatography and in three of six patients using ultrasound. Among the patients in whom two localizing techniques were used, tumor cells were not aspirated (false-negative) in one patient using angiography and ultrasound and in a second patient using both ultrasound and endoscopic retrograde pancreatography. Positive cytology was obtained in a total of 10 patients, the diagnostic yield being 77%. There were a total of three false-negative and no false-positive diagnoses. Cytological diagnosis of pancreatic carcinoma can be made accurately by percutaneous fine needle aspiration of the tumor and operative intervention may be avoided in those patients who do not require operative bypass procedures. Percutaneous fine needle aspiration can be used with equal facility with arteriography, ultrasound, or endoscopic retrograde pancreatography.

6362 THE DIAGNOSIS OF THE SMALL RESECTABLE PANCREATIC CARCINOMA. (Eng.) Ariyama, J.; Shirakabe, H.; Ikenobe, H.; Kurosawa, A.; Owman, T. (Dept. Gastroenterology, Juntendo Univ., Tokyo, Japan). *Clin. Radiol.* 28(4):437-444; 1977.

The use of endoscopic retrograde cholangiopancreatography (ERCP) in combination with angiography for the preoperative diagnosis of 31 of 32 pancreatic carcinomas is reported. In 19 cases, the tumor affected the head, in 11 cases, the body and/or tail, and in 2 cases, the entire pancreas. Of the 32 cases of pancreatic carcinoma, 10 were resectable. Of these, eight were located in the head, one in the body, and one in the tail of the pancreas. Of the 10 cases that were resected, 6 (5 in the head and 1 in the body of the pancreas) were regarded as small carcinomas (less than 2 cm in diameter). The ERCP findings in these six cases of small carcinoma were occlusion of the main pancreatic duct in three cases, stenosis of the main pancreatic duct in two cases, and rarefaction of pancreatic duct branches with a normal main pancreatic duct in one case. In all cases of small pancreatic carcinoma, superselective angiography was necessary to make a definitive diagnosis. Angiographic findings were arterial encasement, occlusion, and an avascular area; these changes were limited to intrapancreatic arteries. While ERCP is the only examination for detecting small pancreatic carcinoma, angiography is indispensable for evaluating the extent and size of the carcinoma, for predicting the resectability of the tumor, and for differentiating between pancreatitis and pancreatic carcinoma.

6363 COMPUTED TOMOGRAPHY IN THE EVALUATION OF PATIENTS WITH SUSPECTED CARCINOMA OF THE PANCREAS. (Eng.) Sheedy, P. F., II; Stephens, D. H.; Hattery, R. R.; MacCarty, R. L. (Mayo Clinic, Rochester, MN 55901). *Radiology* 124(3):731-737; 1977.

Results obtained with computed tomography (CT) in the evaluation of 151 patients with suspected pancreatic carcinoma are reported. The CT diagnoses were divided into four categories based on the original interpretation: mass or carcinoma (53 scans); normal pancreas (68 scans); normal pancreas, but another pathologic process discovered on CT (20 scans); and unsatisfactory or indeterminate examinations (10 scans). Subsequent surgery, biopsy, or clinical follow-up verified the presence of carcinoma in 31 of 53 scans positive for carcinoma. Carcinoma of the pancreas was not observed in 21 patients with positive scans, but in 12 of these patients, surgery or angiography revealed a significant mass lesion near the pancreas. No pancreatic disease was found at surgery in nine patients with scans positive for carcinoma. Significant pancreatic disease was found in 2 of 68 patients with scans showing normal pancreas; surgery revealed a 5-cm carcinoma in the uncinate process in 1 patient, and autopsy revealed acute hemorrhagic pancreatitis in the other. There were 5 proven carcinomas in 10 patients with CT scans that were unsatisfactory or indeterminate. In these 10 cases, there was contrast material or gas artifacts in 4, ascites and postoperative adhesions in 3, excessive "noise" in 1, and "cuts" too low in the abdomen in 1. One patient did not fit the scanner. In cases of erroneously positive examinations where surgery or angiography revealed mass lesions that simulated pancreatic carcinoma, an accumulation of experience and refinement of technique should permit the accurate differentiation of several lesions. In other false-positive cases, refinement of technique, including the increased use of oral contrast material, examinations using overlapping slices, and improvement of equipment function, should result in substantially fewer false-positive interpretations.

6364 LATE-ONSET INTESTINAL OBSTRUCTION IN CYSTIC FIBROSIS--MECONIUM ILEUS EQUIVALENT. (Eng.) Edge, W. E. B.; Nuss, D.; Loening, W. E. K. (1521 Durdoc Centre, 460 Smith St., Durban, South Africa). *S. Afr. Med. J.* 52(7):271-274; 1977.

The cases of four patients with cystic fibrosis who were treated surgically for late-onset bowel obstruction (meconium ileus equivalent) are presented. The patients included an 11-week-old girl, an 8-month-old girl, a 12.5-month-old boy, and a 16-yr-old boy. The fecal impaction occurred in the midjejunum, terminal ileum, terminal ileum, and cecum in each patient, resp. The obstruction was associated with a decrease in the usual dose of pancrelipase in the third patient and with dehydration in the first. In patients 1 and 2, no pancreatic supplements had yet been given, while in patient 4 severe dietary fat restriction appeared to play a major role. The diagnosis of obstruction was made in all cases by review of the patients' history and by the abdominal films. The latter showed the typical appearance of small bowel obstruction as well as the ground-glass or soap-bubble appearance usually associated with meconium ileus. Conservative treatment (the administration of Gastrografin by nasogastric tube and enema) was attempted only in patient 3, but this failed to dislodge the obstruction. All patients recovered after surgery. The authors recommend that conservative management be tried before surgery.

6365 SPONTANEOUS HEMORRHAGE DUE TO PSEUDOCYSTS OF THE PANCREAS. (Eng.) Wu, T. K.; Zaman, S. N.; Gullick, H. D.; Powers, S. R., Jr. (Veterans Admin. Hosp., Albany, NY 12208). *Am. J. Surg.* 134(3):408-410; 1977.

The cases of three patients with spontaneous hemorrhage due to pancreatic pseudocysts are presented. The first patient, a 57-yr-old man, presented with pain in the high lumbar area associated with intermittent chills and fever for 5 weeks. Abdominal exploration revealed a retropancreatic cystic mass connected to the abdominal aorta with a perforation measuring approximately 2 cm in diameter. A portion of the abdominal aorta including the perforation was resected and replaced with a Dacron graft, but the patient died 4 hr after surgery. The pancreatic pseudocyst was first discovered at autopsy. The cyst occurred at the area of uncinate process dorsal to the superior mesenteric artery; it was firmly attached to the abdominal aorta, and the site of perforation was infrarenal. In the second patient, a 58-yr-old man with liver cirrhosis, erosion of the superior pancreaticoduodenal artery was diagnosed preoperatively by selective angiography. The gastroduodenal artery was ligated before the cyst was opened. Although there was no fistula detected between the pseudocyst and the gastrointestinal tract, it is likely that the patient's previous episodes of gastrointestinal bleeding originated from the pseudocyst. In the third patient, a 56-yr-old woman, a ruptured pseudocyst was discovered at laparotomy with hemorrhage into the retroperitoneal space. As in the second patient, dissection of the aorta below the diaphragm to obtain adequate control was essential before the pseudocyst was manipulated. After gastroduodenal artery ligation, the bleeding was controlled by suture-ligating the bleeder from the inside of the cyst. Surgery was successful in the last two patients. These cases indicate that operative treatment of this condition offers a better prognosis than more conservative management.

6366 PANCREATIC PSEUDOCYSTS COMMUNICATING WITH THE STOMACH: DEMONSTRATION BY ENDOSCOPIC RETROGRADE PANCREATOGRAPHY. (Eng.) Sugawa, C.; Walt, A. J.; Sankaran, S.; Bouwman, D.; Weaver, D. (Wayne State Univ., 540 E. Canfield Ave., Detroit, MI 48201). *Arch. Surg.* 112(9):1050-1053; 1977.

The cases of four patients in whom pancreatic pseudocysts communicating with the stomach were demonstrated by endoscopic retrograde pancreatography (ERP) are presented. The patients ranged in age from 34 to 57 yr. Alcoholic pancreatitis was the cause of the pseudocyst in all patients. Two patients presented with nausea, vomiting, and epigastric pain; one presented with epigastric pain alone and one presented with progressive abdominal distention. In one patient, a repeat ERP revealed that the pseudocyst had spontaneously drained into the stomach, and surgery was unnecessary. Distal pancreatectomy was successful in the treatment of one patient with pancreatic ascites and one patient with a left-sided pleural effusion. None of the patients had a pseudocyst converted into a pancreatic abscess. No unusual inflammatory features were seen in the two operated patients. These cases emphasize the potential diagnostic value of ERP in determining the presence and the fate of pseudocysts.

6367 CT DEMONSTRATION OF THE SPLENIC VEIN--PANCREATIC RELATIONSHIP: THE PSEUDO-DILATED PANCREATIC DUCT. (Eng.) Seidelmann, F. E.; Cohen, W. N.; Bryan, P. J.; Brown, J. (Upstate Medical Center, Syracuse, NY 13210). *Am. J. Roentgenol.* 129(1):17-21; 1977.

The cross-sectional anatomy of the splenic vein-pancreatic relationship, as visualized by computed tomography, was studied in 86 patients who had undergone abdominal scanning. A layer of fat that is normally present between the splenic vein and the pancreas may simulate a dilated pancreatic duct. Distinct demonstration of the splenic vein as a structure separate from the pancreas was possible in 43 of the 86 patients. An additional 25% of the patients had partial or indistinct demonstration of the splenic vein. Appreciation of this normal relationship on CT is imperative to avoid misinterpretation of the fat layer as a dilated pancreatic duct. In addition, the measured size of the pancreas may be overestimated by addition of the splenic vein width if the intervening fat is not identified.

6368 PROPHYLAXIS AND TREATMENT OF POSTOPERATIVE COMPLICATIONS IN PANCREATIC NECROSIS. (Rus.) Shigarev, T. D. (N. A. Semashko Municipal Emergency Hosp., Orel, USSR). *Khirurgiia* (3):114-116; 1977.

6377 STATISTICAL METHODS FOR QUANTIFYING THE SEVERITY OF CLINICAL ACUTE PANCREATITIS. (Eng.) Ranson, J. H. C.; Pasternack, B. S. (New York Univ. Medical Center, 550 First Ave., New York, NY 10016). *J. Surg. Res.* 22(2):79-91; 1977.

A statistical study was done of factors that have substantial prognostic value for identifying high-risk patients with acute pancreatitis. Two groups of patients were studied. Group 1 consisted of 244 patients who recovered without any major life-threatening complication, and group 2 consisted of 56 patients with severe pancreatitis of whom 22 died. Twelve variables were associated with increased risk of death or serious illness, and nine of them led to correct classification of 96% of the patients. These nine variables are age, blood sugar, SGOT, number of previous episodes, LDH at the time of admission, hematocrit fall, lowest serum calcium, lowest arterial oxygen tension, and estimated fluid sequestration during the initial 48 hr after admission. The variables most strongly related to severity of disease were LDH (group 1, 230.8 ± 133.7; group 2, 449.6 ± 394.5), blood sugar levels (group 1, 144.8 ± 50.2; group 2, 216.2 ± 108.1), and SGOT (group 1, 136.4 ± 184.2; group 2, 234.0 ± 443.4). An accurate prediction of death or serious illness was possible using these nine factors and their interrelationships.

6378 THE EFFECTS OF SOMATOSTATIN ON HORMONAL AND METABOLIC RESPONSES IN CHRONIC PANCREATITIS. (Eng.) Botha, J. L.; Vinik, A. I.; Le Roith, D.; Child, P. T.; Jackson, W. P. U. (Dept. Medicine, Univ. Cape Town, South Africa). *S. Afr. Med. J.* 51(24):872-875; 1977.

The effects of somatostatin on the immunoreactive glucagon responses to arginine and insulin-induced hypoglycemia were studied in five normal men and five men with chronic pancreatitis. Unmodified synthetic somatostatin (200/μg, i.v. bolus + 200 μg infused over 3 hr) had no effect on basal plasma insulin and pancreatic glucagon-like immunoreactivity (GLI) levels in controls or patients. Somatostatin inhibited insulin-hypoglycemia-induced pancreatic GLI release in controls and in patients with pancreatitis, and prolonged the insulin-induced fall in blood glucose in the patients. Arginine (10 mg/kg/min, i.v., 30 min) caused a decrease in free fatty acids (FFA) in controls, which was inhibited by somatostatin. Somatostatin abolished the rebound rise in plasma FFA in patients with pancreatitis after insulin-hypoglycemia. This effect may be related to inhibition of pancreatic GLI release or may be a direct action of somatostatin on lipolysis.

6379 DIABETES AND HYPOGLYCEMIA IN CHRONIC PANCREATITIS. (Eng.) Linde, J.; Nilsson, L. H.; Barany, F. R. (St. Erik's Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 12(3):369-373; 1977.

The frequency of diabetes and hypoglycemia was studied in 59 patients with chronic pancreatitis, and the hypothesis that insulin sensitivity associated with pancreatitis is due to a destruction of α_2-cells, resulting in glucagon deficiency, was tested. Overt diabetes occurred in 36 patients. Half of the diabetics were insulin-dependent; among these patients, labile diabetes with hyperglycemia and high amounts of glucose in the urine was not uncommon. Hypoglycemic episodes were noted in 14 of the 18 insulin-treated patients, and in 3 patients severe hypoglycemia was believed to be the cause of death. Pancreatic glucagon was measured in the plasma of two patients with pancreatic diabetes and severe brain damage following hypoglycemic coma. Low basal glucagon values (0.12 and 0.17 ng/ml) were found, and the normal rise upon insulin-induced hypoglycemia was not seen. The results suggest that glucagon should be used in the management of severe hypoglycemia in chronic pancreatitis, and a certain degree of hyperglycemia should be allowed in the treatment of diabetes in these patients.

6380 COLONIC NECROSIS COMPLICATING PANCREATITIS. (Eng.) Dallemand, S.; Farman, J.; Stein, D.; Waxman, M.; Mitchell, W. (Downstate Medical Center, 450 Clarkson Ave., Brooklyn, NY 11203). *Gastrointest. Radiol.* 2(1):27-30; 1977.

Two cases are presented of colonic necrosis resulting from acute pancreatitis, with particular attention to the radiologic findings. The first patient, an 86-yr-old man, presented with abdominal pain and guaiac-positive stool. Plain abdominal x-ray demonstrated several dilated small bowel loops and colon extending to the splenic flexure, and a barium enema examination revealed spasm and poor distention in the proximal descending colon. Laparotomy revealed an edematous pancreas and a necrotic descending colon. Pathologic examination of the resected colon confirmed extensive omental and serosal fat necrosis. The descending colon was altered because of hemorrhagic necrosis of all intestinal layers with only minimal acute inflammation. Several serosal veins were occluded by thrombi. Splenectomy was performed in the second patient, a 14-yr-old boy who had sustained a lacerated spleen in an automobile accident. All other abdominal organs were normal. An upper gastrointestinal and small bowel series were carried out after he developed watery diarrhea and abdominal pain. Ischemic changes were noted in the distal small bowel, cecum, and ascending colon. Arterial occlusions were evident at selective superior mesenteric arteriography. At laparotomy the cecum and ascending colon were necrotic and a longitudinal perforation was identified with barium spillage in the peritoneal cavity. Widespread fat necrosis was present in the peritoneal cavity and also involved the omentum. The pancreas was markedly swollen and edematous. The thrombi demonstrated angiographically were identified in the ileocolic artery and mesenteric branches to the ascending colon. Involvement of the mesenteric branches in pancreatitis was probably responsible for the intestinal ischemia in these patients.

LIVER AND BILIARY TRACT

6393 THE USE OF PROSTAGLANDIN F_2 ALPHA IN SELECTIVE HEPATIC ANGIOGRAPHY. (Eng.) Legge, D. (Mater Misericordiae Hosp., Dublin, Ireland). *Radiology* 124(2):331-335; 1977.

The results of slow infusion hepatic angiographic studies obtained before and after the intra-arterial injection of prostaglandin F_2 alpha (60 µg) in 50 patients were compared. The prostaglandin injection resulted in increased caliber of the hepatic arteries, increased opacification of the parenchyma of the liver, and improved visualization of the gallbladder wall. Poorly vascularized metastatic lesions were better shown on the prostaglandin studies, and carcinoma of the gallbladder was diagnosed in two instances. The demonstration of 12 highly vascularized metastatic tumors was enhanced on the prostaglandin studies, but further improved after the injection of angiotensin (1 µg). The use of slow infusion hepatic angiography, augmented by prostaglandin, should reduce the diagnostic error rate for poorly vascularized hepatic tumors, and should aid the preoperative diagnosis of gallbladder carcinoma.

6394 A SIMPLE ULTRASONIC METHOD FOR EVALUATING LIVER SIZE. (Eng.) Holmes, J. H.; Sundgren, C; Ikle, D; Finch, J. (Univ. Colorado Medical Center, 4200 E. Ninth Ave. No. C277, Denver, CO 80262). *J. Clin. Ultrasound* 5(2):89-91; 1977.

A simple semiquantitative index, relating liver size of a specific patient to the normal range, is described. By measuring the liver area (maximum section) and plotting this against intra-abdominal area at the same level, tolerance levels were calculated for 80% of 63 normal subjects with a 95% confidence. The use of this method in 14 patients with liver diseases was also demonstrated. Eight patients fell within normal range. Six patients fell outside the normal range; these included one with idiopathic hepatomegaly, one with liver abscess, one with metastasis, one with obstructive jaundice, one with pancreatic tumor, and one with leiomyosarcoma. While liver size changes may be of limited diagnostic value in liver disease, the regression technique seems to be a simple approach to the estimation of liver size.

6395 ASSESSMENT OF ANTITOXIC LIVER FUNCTION BY ^{131}I-ORTHO-IODO-BENZOIC ACID. (Rus.) Dognalek, J.; Eisselt, M. (Medical Faculty, J. E. Purkinje Univ., Brno, Czechoslovakia). *Med. Radiol. (Mosk.)* 22(4):42-47; 1977.

The efficacy of an ^{131}I-ortho-iodo-benzoic acid (^{131}I-OIBA) metabolism assay for the assessment of hepatic antitoxin function was tested in more than 2,500 patients. The patients received the preparation on an empty stomach (2 mg, p.o., 20-30 μCi); OIBA metabolites were separated electrophoretically in the daily urine. It was found that the patients with chronic liver lesions had increased glucuronidation (binding of the foreign substances with glucuronic acid and formation of the glucuronides). Glucuronidation was significantly decreased in the patients with nontumoral lesions subjected to surgery under prolonged anesthesia; this was probably due to the liver hypoxia.

6396 METABOLISM OF FLURAZEPAM BY THE SMALL INTESTINE.

(Eng.) Mahon, W. A.; Inaba, T.; Stone, R. M. (Toronto General Hosp., Toronto, Ontario M5G 1L7, Canada). *Clin. Pharmacol. Ther.* 22(2):228-233; 1977.

The metabolism of 5-^{14}C-flurazepam was studied in three patients following catheterization of the portal and hepatic veins. Flurazepam (1.4-1.5 mg) was administered through a tube into the stomach in one patient and into the duodenum in two patients. Thin-layer chromatographs of portal vein blood showed that there was a rapid and early appearance of metabolites of flurazepam, consistent with the metabolism of the flurazepam by the intestinal mucosa, and at times when the concentrations in the hepatic vein and peripheral blood were very much lower than those in the portal vein. The major metabolites identified in portal vein blood were the mono- and didesethyl metabolites of flurazepam. Considerable hepatic uptake of flurazepam and its metabolites occurred, as evidenced by the lower concentrations of the parent compound and metabolites in the hepatic vein. Thus, "first-pass" metabolism of flurazepam following p.o. administration occurs in the small bowel mucosa of man as well as in the liver.

6397 EFFECT OF PHENOBARBITAL ON BILIARY LIPID METABOLISM IN NORMAL MAN.

(Eng.) Ginsberg, R. L.; Garnick, M. B. (Baltimore City Hosp., 4940 Eastern Ave., Baltimore, MD 21224). *Gastroenterology* 72(6):1221-1227; 1977.

The effect of phenobarbital on biliary lipid composition in humans without gallbladder disease was investigated by determining parameters of biliary lipid metabolism in eight healthy subjects before and after p.o. phenobarbital administration (3 mg/kg/day for 25-54 days). Phenobarbital did not produce any statistically significant changes in bile lipid composition; cholesterol saturation index; total bile acid pool size; daily fractional turnover rate of cholic acid; hepatic secretion rates of cholesterol, bile acids, or phospholipids; and the fraction of the total bile acid pool represented by individual bile acids. Therefore, phenobarbital is not an effective agent, at least when used alone, in inducing changes in bile lipid composition during short-term administration in normal man. This indicates that phenobarbital would not be a useful modality in the prevention of the development of cholesterol gallstones; its prophylactic value in subjects with bile of higher lithogenicity cannot be predicted from these studies.

6398 MAJOR HEPATIC RESECTION AND PORTAL PRESSURE.

(Eng.) Buerk, C. A.; Putnam, C. W.; Starzl, T. E. (Univ. Colorado Medical Center, Denver, CO). *Surg. Gynecol. Obstet.* 144(6):853-854; 1977.

Portal pressures were obtained before and after resection in three patients undergoing hepatic trisegmentectomy in whom 80% or more of the liver was removed. The patients' case reports are presented. The preoperative portal pressures (taken through a portal vein cannula at surgery, before extensive dissection) were 180, 200, and 160 mm of saline, resp., in the three patients (a 57-yr-old man, a 40-yr-old woman, and a 12-yr-old girl). After completion of the resections, the portal vein pressures in the respective patients were 172, 195, and 154 mm saline. No hypotension occurred during any of the procedures, the central venous pressures remained relatively constant, and there was no evidence of splanchnic engorgement. Although other reports have stressed the inevitability of portal hypertension and splanchnic pooling following major liver resections, with careful anatomic dissection and the absence of clinical disease in the nonresected remnant, major hepatic resections produce no clinical evidence of increased portal pressure or splanchnic sequestration.

6399 ALPHA-1-ANTITRYPSIN GLOBULES IN THE LIVER AND PiM PHENOTYPE.

(Eng.) Bradfield, J. W. B.; Blenkinsopp, W. K. (St. Mary's Hosp., London W2, England). *J. Clin. Pathol.* 30(5):464-466; 1977.

The case of a patient with typical alpha-1-antitrypsin globules in the hepatocytes but a normal serum antitrypsin level and a normal phenotype (PiM) for alpha-1-antitrypsin is presented. The patient, a 79-yr-old man, was hospitalized with non-alcoholic acute pancreatitis. A liver biopsy specimen showed PAS-positive, diastase-resistant globules in the periportal hepatocytes, but no further abnormalities other than excess fat. The globules were identified as alpha-1-antitrypsin by both immunofluorescent and immunoperoxidase methods. The serum antitrypsin level was 2.3 g/l. Phenotyping of antemortem serum and postmortem blood showed the PiM allele, with no evidence of an abnormal allele, on starch gel electrophoresis. Isoelectric focusing confirmed that only the PiM allele was present. The identification of alpha-1-antitrypsin globules can no longer be regarded as conclusive evidence of an abnormal alpha-1-antitrypsin phenotype.

6400 CORRELATIONS BETWEEN THROMBOCYTE COUNT, CLINICAL DIAGNOSIS AND LIVER HISTOLOGY IN PATIENTS WITH CHRONIC LIVER DISEASES.

(Ger.) v. Braun, H. H.; Henning, H.; Luders, C. J.; Probst,

P. (Klinik Fohrenkamp der BfA, Postfach 13 80, 2410 Molln/Lauenburg, W. Germany). *Z. Gastroenterol.* 14(5):538-547; 1976.

The blood thrombocyte content and the histologic findings were compared in 1,488 patients with chronic liver disease. The degree of hepatic injury ranged from fatty infiltration to fatty cirrhosis or from slightly active chronic hepatitis to active postnecrotic cirrhosis. The extent of liver injury (i.e., the presence of cirrhosis) was correlated with a significant decrease in the thrombocyte count. Thrombocytopenia was also present in cases of nonactive liver disease and in posthepatic status. Histologic examination of liver biopsy specimens showed that the thrombocytopenia occurred in cases in which cirrhotic transformation, connective tissue proliferation in the periportal folds, or inflammatory activity had occurred. It is concluded that the decreased thrombocyte count in cirrhosis is related to increased thrombocyte storage in the spleen; this may be due to the altered portal blood flow occurring with portal hypertension. This study demonstrates that there is a correlation between the degree of liver injury, portal pressure, platelet pooling, and the thrombocyte count.

6401 SERUM IgE LEVELS IN PATIENTS WITH LIVER DISEASE. (Eng.) Joske, R. A.; Turner, K. J.; Murphy, B. P. (Perth Medical Center, Shenton Park, Western Australia 6008). *Med. J. Aust.* 2(15):555-557; 1977.

The relation between IgE and the diagnosis and therapy of liver diseases was studied in 120 patients and 413 healthy controls. The patients included 26 with untreated active chronic hepatitis, 36 with treated active chronic hepatitis, 14 with acute hepatitis, 33 with alcoholic liver disease, 10 with congestive hepatomegaly, 14 with neoplastic disease, 17 with obstructive syndromes, and 10 with miscellaneous liver diseases. The mean serum IgE level in the patients (1,215 μg/l) was significantly higher than that in the controls (351 μg/l, $p<0.01$). There was a significant increase in IgE levels in untreated active chronic hepatitis ($p<0.05$), and the IgE levels fell significantly with treatment, so that IgE levels in the treated patients did not differ significantly from those in the control group. The mean IgE level in the patients with alcoholic liver disease (1,638 μg/l) was significantly higher than that in controls ($p<0.05$). There were no significant alterations in IgE levels in other types of acute or chronic liver disease. There were no significant correlations between IgE levels and the age or sex of the patients, or between IgE levels and other laboratory investigations (i.e., eosinophil counts, serum bilirubin, alkaline phosphatase, SGOT, serum albumin, total serum globulin, serum γ-globulin, serum IgA, serum IgG, serum IgM, and the presence or absence of hepatitis B antigen or tissue autoantibodies). It seems improbable that reaginic antibody is important in liver disease generally, or that the liver plays a role in the metabolism of IgE.

6402 ALPHA$_1$-ANTITRYPSIN DEFICIENCY IN CHRONIC LIVER LESIONS. (Pol.) Szczeklik, A.; Stachura, J.; Szczudrawa, J.; Sowa, J.; Wozny, E.; Bogdal, J.; Pieton, R. (Clinic Allergy and Immunology, Inst. Internal Medicine, Krakow, Poland). *Pol. Tyg. Lek.* 32(27):1033-1036; 1977.

The content of serum antitrypsin was assessed in 96 patients with various chronic liver lesions. Clinical and histological diagnosis was of chronic active hepatitis in 28 patients, chronic persisting hepatitis in 15, portal cirrhosis in 24, postnecrotic cirrhosis in 16, primary biliary cirrhosis in 1, liver steatosis in 6, and hepatocarcinoma in 4; 2 patients were not accounted for. Alpha$_1$-antitrypsin (AAT) level was significantly elevated in 93 patients, all of whom had MM phenotype, while 3 patients with MZ phenotype showed AAT deficiency; clinically, 2 had liver fibrosis and 1 had hemosiderosis of the hepatocytes.

6403 SERUM ALPHA-FETOPROTEIN LEVELS AFTER HEPATIC ARTERY LIGATION AND POSTOPERATIVE CHEMOTHERAPY: CORRELATION WITH CLINICAL STATUS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA. (Eng.) Nagasue, N.; Inokuchi, K.; Kobayashi, M.; Saku, M. (Kyushu Univ. Sch. Medicine, Higashiku, Fukuoka 812, Japan). *Cancer* 40(2):615-618; 1977.

Eight patients with hepatocellular carcinoma and positive serum alpha-fetoprotein (AFP) levels were treated by hepatic artery ligation and postoperative chemotherapy. After these procedures, changes in serum AFP levels were studied, and the value of AFP in the clinical assessment of treatment was investigated. Three patterns of clinical response were discerned. First, a marked decrease in AFP levels was found in five patients following the treatment. Three of these patients are alive, all with lowered or normal serum AFP levels at 20, 22, and 60 weeks after operation. Second, two patients displayed only a transient decrease in AFP levels followed by a gradual increase. Third, there was a continuous increase in AFP levels in one patient who showed no clinical improvement. The serum AFP levels in each case appeared to correlate with the prognosis of these patients. Therefore, serial measurements of AFP levels may provide an index to assess the clinical result of hepatic artery ligation in patients with hepatoma.

6404 SERUM ALPHA FETOPROTEIN IN HEPATOCELLULAR CARCINOMA. (Eng.) Chen, D. S.; Sung, J. L. (Natl. Taiwan Univ. Hosp., 1-Chang-Te St., Taipei, China 100). *Cancer* 40(2):779-783; 1977.

The serum alpha-fetoprotein level (AFP) was determined by double immunodiffusion and radioimmunoassay in 125 histologically verified cases of hepatocellular carcinoma, 66 other malignancies, 74 cases of liver cirrhosis, 60 of chronic aggressive hepatitis, 12 of chronic persistent hepatitis, 16 of subacute hepatitis, 36 of acute viral hepatitis, and 13 healthy hepatitis B surface antigen (HBsAg) carriers. AFP greater than 10 ng/ml appeared in 90% of the 125 patients with hepatocellular carcinoma and was above 400 ng/ml in 69%. In 80% of those above 400 ng/ml, AFP was demonstrated by immunodiffusion. The AFP level in hepatocellular carcinoma declined as age increased. It also appeared to be related to the tumor cell type; the relatively immature cell type was more frequently associated with a higher AFP level. The presence of HBsAg did not influence the AFP level. Although the AFP in other malignancies and liver diseases was abnormal in 14%-69%, the level did not exceed 400 ng/ml. It appears that an AFP level of 400 ng/ml or greater is useful in the diagnosis of hepatocellular carcinoma.

6405 EXCESSIVE ALPHA-FETOPROTEIN CONCENTRATIONS IN HEPATOCELLULAR CARCINOMA. (Eng.)

Amery, A. H.; Alston, W. C.; Kohn, J.; White, W. F. (Frimley Park Hosp., Frimley, Surrey GU16 5UJ, England). *Br. Med. J.* 2(6087):611-612; 1977.

The case of a patient with hepatocellular carcinoma, whose serum concentration of alpha-fetoprotein exceeded 4,800,000 μg/1 and whose serum produced an extra band on protein electrophoresis is presented. The patient, a 16-yr-old boy, presented with a 2-week history of abdominal distention and right shoulder pain. Ascites, hepatomegaly, and increased serum bilirubin, alkaline phosphatase, and transaminase levels were present. The initial alpha-fetoprotein level of 4,800,000 g/l increased to 7,400,000 g/l during i.v. alimentation. Upon serum protein electrophoresis on cellulose acetate, the serum formed an extra band between albumin and alpha$_1$-globulin. Despite treatment with x-irradiation and a course of doxorubicin, the patient died 5 months after presentation. The maximum alpha-fetoprotein concentration in this patient is thought to be the highest ever reported. To appear as a separate band on routine electrophoresis, alpha-fetoprotein must be present in a concentration exceeding 0.5 g/l.

6406 INFANTILE HEPATIC HEMANGIOENDOTHELIOMAS ASSOCIATED WITH HEMIHYPERTROPHY. (Eng.)

Wood, B. P.; Putnam, T. C.; Chacko, A. K. (Univ. Rochester Medical Center, 601 Elmwood Ave., Rochester, NY 14642). *Pediatr. Radiol.* 5(4):242-245; 1977.

The case of an infant with marked hemihypertrophy, multiple liver hemangioendotheliomas, and a thoracic paraspinal hemangioendothelioma is presented. The infant, a 10-month-old girl, had congenital left-sided hemihypertrophy, hepatomegaly, and a low thoracic paraspinal mass at presentation. A liver scan showed multiple defects in the uptake of radioisotope. Surgical exploration revealed multiple infantile hemangioendotheliomas of the liver and a paraspinal hemangioendothelioma. A review of 69 reported cases of infantile hemangioendothelioma of the liver and viscera revealed no previous reports of hemihypertrophy associated with this abnormality.

6407 THE PATHOLOGY OF LIVER CELL CANCER. (Eng.)

Cameron, H. M. *In: Liver Cell Cancer.* Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Co.): pp. 17-43; 1976.

A description of the gross and microscopic pathology of liver cell cancer, its routes of spread, and differential diagnosis is presented. The gross pathology of liver cell cancer may be nodular (multiple nodules, often widely dispersed), massive (one dominant large mass from which there is a variable degree of spread, usually as nodules, into the neighboring parenchyma), or, less commonly, diffuse (extensive, fine, non-nodular infiltration). Microscopically, hepatocellular carcinoma is most commonly a well-differentiated tumor, bearing resemblance to the parent tissue. Because of the high degree of differentiation in most liver cell carcinomas, diagnosis is usually straightforward if representative tissue is available. Hepatocellular carcinoma can be distinguished from cholangiocarcinoma, since the latter is seldom multifocal and tends to invade the surrounding parenchyma in an irregular fashion that differs from the rounded lobulated masses seen in most hepatocellular tumors. Liver cancer spreads by local extension and by invasion of venous and lymphatic channels. It enlarges centrifugally, advancing into neighboring parenchyma, which has been devitalized by pressure and by derangement of its blood supply. There may also be perisinusoidal invasion with tumor cells replacing liver cell plates. Hepatocellular carcinoma is commonly associated with liver cirrhosis, most commonly of the macronodular type (posthepatic or postnecrotic). In liver cell cancer accompanied by cirrhosis, there may be an increase in the frequency of diabetes according to one study, which found diabetes in 23% of such cases, but in only 7.8% of cancers without cirrhosis. There is also a recognized association between liver cell cancer and hemochromatosis. Ectopic hormone syndromes ascribed to liver cell cancer are polycythemia, hypoglycemia, hypercalcemia, the carcinoid syndrome, and excess secretion of gonadotropins.

6408 SURGICAL TREATMENT OF PRIMARY LIVER CARCINOMA. (Eng.)

Flatmark, A.; Frethem, B.; Knutrud, O.; Lande, G. (Natl. Hosp. Norway, Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(5):571-575; 1977.

The management and surgical treatment of 45 patients with primary liver carcinoma during a 15-yr period were reviewed. Sixteen patients were less than 15 yr of age. All patients underwent diagnostic laparotomy, and liver resection was performed in 16 (36%). Resectability was higher in children than in adults. Left lobectomy was performed in eight patients, right lobectomy in three, and an extended right lobectomy in five patients. One patient died postoperatively. Of the surviving 15 patients, 4 died from metastatic tumor within 18 months after surgery. Patient survival at 2 yr was 73%. The results indicate radical surgery or primary liver carcinoma whenever possible.

6409 RECURRENT MASSIVE HAEMORRHAGE FROM BENIGN HEPATIC TUMOURS SECONDARY TO ORAL CONTRACEPTIVES. (Eng.) Bein, N. N.; Goldsmith, H. S. (Thomas Jefferson Medical Coll., 1025 Walnut St., Philadelphia, PA 19107). *Br. J. Surg.* 64(6):433-435; 1977.

The case of a patient who, while taking oral contraceptives, had a hepatic hemorrhage from an adenoma 3 yr after an initial hepatic hemorrhage is presented. The patient, a 34-yr-old woman with an 11-yr history of taking oral contraceptives, had intraperitoneal bleeding following a traumatic hepatic laceration. At laparotomy, the liver was enlarged, and a 4.5 x 4 x 3 cm mass was removed from the right lobe; this was described as showing "focal nodular hyperplasia." She continued to take oral contraceptives and remained well for 3 yr. At this time, massive hepatic hemorrhage recurred, and a massive lesion involving the entire right lobe was found. She underwent resection of the entire right and medial segments of the left hepatic lobes. A 4-cm mass located deep within the remaining part of the liver was left intact. The final histological diagnosis of the liver mass was hepatic adenoma with necrosis and hemorrhage. The patient has refrained from taking oral contraceptives since surgery. A hepatic arteriogram taken 8 months after operation showed that the liver adenoma that had been left intact had decreased 25% in size in relation to a preoperative arteriogram. Any patient taking oral contraceptives who presents with right upper quadrant pain, hemoperitoneum, and vascular collapse must be considered to be bleeding from an hepatic tumor until proved otherwise.

6410 CAROLI'S DISEASE: AN ULTRASONIC DIAGNOSIS. (Eng.) Bass, E. M.; Funston, M. R.; Shaff, M. I. (Groote Schuur Hosp., Observatory, Cape Town 7925, South Africa). *Br. J. Radiol.* 50(593):366-369; 1977.

The case of a patient in whom Caroli's disease was diagnosed by ultrasonography and confirmed by transhepatic cholangiography is presented. The patient, a 19-yr-old woman, experienced recurrent episodes of jaundice and rigors. She was first thought to have infectious hepatitis, but her jaundice never settled and a liver biopsy was compatible with cholangitis and biliary stasis. When she became pyrexial and her liver was enlarged by 3 cm, longitudinal and transverse grey-scale ultrasonography was carried out. Four transonic lesions, varying from 2-5 cm in diameter, were detected in the region of the porta hepatis; their cystic nature was confirmed by the absence of internal echoes at high and low gain and clear definition of their posterior walls. An undilated gallbladder was identified, and superior to the gallbladder and within the liver substance were three cystic lesions. The diagnosis of congenital cystic dilatation of the intrahepatic bile ducts was confirmed by transhepatic cholangiography and at surgery. A 6-cm diameter choledochal cyst containing 12 calculi was found, and a cholecystectomy and Roux-en-Y choledocystjejunostomy were carried out.

6411 STIMULATION OF DRUG METABOLISM BY RIFAMPICIN IN PATIENTS WITH CIRRHOSIS OR CHOLESTASIS MEASURED BY INCREASED HEXOBARBITAL AND TOLBUTAMIDE CLEARANCE. (Eng.) Zilly, W.; Breimer, D. D.; Richter, E. (Luitpoldkrankenhaus, Josef-Schneider-Str. 2, D-8700 Wurzburg, W. Germany). *Eur. J. Clin. Pharmacol.* 11(4):287-293; 1977.

The enzyme-inducing ability of rifampicin was studied in 11 patients with liver cirrhosis or cholestasis, and the ability of this drug to improve hepatocellular function was assessed. The patients received rifampicin, p.o., in a dose increasing from 150 mg to 600 mg daily for 7-132 days. Ten patients received hexobarbital (7.32 mg/kg) and five received tolbutamide (20 mg/kg) by i.v. infusion prior to and after rifampicin treatment; plasma concentrations of the two test compounds were determined during and after infusion. The average elimination half-life of hexobarbital decreased from 624 to 262 min, and that of tolbutamide from 292 to 160 min, following rifampicin treatment. The metabolic clearance of hexobarbital increased more than twofold and that of tolbutamide almost twofold. The results suggest that rifampicin stimulates hepatic drug metabolism in patients with liver disease. The induction did not lead to improvement of hepatocellular function during disease, as judged by laboratory findings.

6412 ACUTE LIVER FAILURE: EXPERIENCE IN A SPECIAL UNIT. (Eng.) Ward, M. E.; Trewby, P. N.; Williams, R.; Strunin, L. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *Anaesthesia* 32(3):228-239; 1977.

The management of acute liver failure is discussed. Clinical manifestations of acute liver failure include neurological, acid-base, cardiac, renal, metabolic, and hematological disturbances. Fetor hepaticus may be present, and the liver is often small on percussion. Clinical jaundice develops over a few days and, in most cases, is preceded by signs of encephalopathy. Specific treatments for the management of acute liver failure include the use of corticosteroids, extracorporeal animal liver perfusion, human cross-circulation, exchange blood transfusion, hepatic transplantation, and hemodialysis. Although each treatment has been successful on occasion, the success of any of these treatments has not been substantiated by controlled trials. Extracorporeal charcoal hemoperfusion has also been used for the treatment of acute liver failure. Total heparinization is important and is achieved by an initial bolus plus intermittent doses of heparin to maintain a Lee-White clotting time of 20-30 min. Initial results with charcoal hemoperfusion in 22 patients showed an improvement in survival rate from 13% to 45%. The major problem presently encountered with charcoal hemoperfusion is hypotension, which generally responds to volume replacement. Recent clinical experience since 1975 with a new hemodialysis membrane prepared from polyacrylonitrile shows this technique to be twice as efficient as charcoal hemoperfusion in clearing toxic water-soluble compounds from the blood. It is also free from many of the side-effects associated with charcoal hemoperfusion. Among 23 patients treated with this new hemodialysis membrane, 9 have survived. The monitoring of patients with acute liver failure includes daily measurements of prothrombin time, plasma bilirubin, aspartate aminotransferase, and alkaline phosphatase. Prothrombin time has proved useful in assessing the return of liver function. Neither serum bilirubin nor hepatic enzyme activity are of prognostic value.

6413 ABNORMAL PLATELET FUNCTION AND ULTRASTRUCTURE IN FULMINANT HEPATIC FAILURE.

(Eng.) Rubin, M. H.; Weston, M. J.; Bullock, G.; Roberts, J.; Langley, P. G.; White, Y. S.; *et al.* (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5, England). *Q. J. Med.* 46(183): 339-352; 1977.

To study the nature of the bleeding diathesis of fulminant hepatic failure, platelet function was studied in 12 patients with severe liver necrosis and fulminant hepatic failure and 16 patients with less severe damage uncomplicated by hepatic coma. Platelets from six patients with severe liver necrosis required a higher concentration (threshold concentration) of ADP to reach second-phase aggregation than those from controls (12.3×10^{-6} M compared with 2.2×10^{-6} M, $p<0.001$). Platelets from another six patients with severe liver necrosis failed to show second phase aggregation at the highest concentration of ADP used (32×10^{-6} M). The degree of aggregation at a fixed ADP concentration (3.2×10^{-6} M) was significantly less than in controls (34.2% compared with 57.5%). Capillary bleeding times correlated positively with the abnormalities of platelet aggregation. In crossover studies, platelet-poor plasma from these patients did not inhibit platelet aggregation in controls, nor did platelet-poor plasma from controls enable patients' platelets to reach second-phase aggregation, suggesting that factors other than the plasma were responsible for this abnormal platelet function. Platelet function was normal in the 16 patients with virus hepatitis or liver damage (without fulminant hepatic failure) following paracetamol overdose. Electron microscopy of platelets from patients with fulminant hepatic failure showed many structural abnormalities, including numerous pseudopods, vacuoles, and blurred plasma membranes. Most striking were the numbers of platelets showing microtubules, and the increased microtubular content per platelet. As patients recovered from fulminant hepatic failure, platelet function improved and platelets with normal ultrastructure appeared among the abnormal ones. The abnormal-looking platelets may be responsible for the abnormalities of platelet function, but kinetic studies are required to elucidate their source and fate.

6414 CONGENITAL HEPATIC FIBROSIS. (Eng.)

Partovi, P. (N. 5901 Lidgerwood, Suite 219, Spokane, WA 99207). *Int. Surg.* 62(6/7):361-363; 1977.

The case of a patient with congenital hepatic fibrosis is presented. Liver cirrhosis was diagnosed at the age of 11 months, and one of his eight siblings had died from hemorrhage from esophageal varices. The patient had mild hypertension that responded to antihypertensive medication. Massive upper gastrointestinal bleeding occurred when the patient was 31. At laparotomy, the spleen and liver were enlarged, and large esophageal varices were present. Engorgement of the splanchnic veins was compatible with portal hypertension. A branch of the superior mesenteric vein was cannulated, and a portal pressure reading of 42 cm of water was obtained; a splenic pulp pressure of 44 cm water substantiated the presence of portal hypertension. An inferior vena cava-superior mesenteric shunt was performed, and splenic pulp pressure dropped to 24 cm of water. A liver biopsy specimen showed a network of dense, fibrous tissue dividing the liver into compartments without distorting the original lobular pattern. The fibrous bands were up to 100 μ thick. The liver cells were normal without evidence of necrosis or any regenerating nodule. The portal triads were normal, but a paucity of portal vein branches was observed. Following the patient's discharge, i.v. pyelography showed typical bilateral polycystic kidneys. About 3 yr after surgery, the patient developed acute strangulating small bowel obstruction, which resulted from adhesions. At this time, hepatosplenomegaly was still present. The mesocaval anastomosis was intact and there were no signs of portal hypertension.

6415 EXCESSIVE HEPATIC GLYCOGEN STORAGE IN GLUCOSEPHOSPHATE ISOMERASE DEFICIENCY.

(Eng.) Van Biervliet, J. P. G. M.; Staal, G. E. J. (Akademische Ziekenhuis, St. Jan, Sint Pieters, Brugge 8000, Belgium). *Acta Paediatr. Scand.* 66 (3):311-315; 1977.

The case of a patient with generalized glucose phosphate isomerase deficiency in whom large amounts of glycogen were found in the liver and RBC is presented. A liver biopsy was carried out after a 15-hr fast. Abundant cytoplasmic glycogen stored as beta particles was still present. The mean mitochondrial volume was normal, although some mitochondria were enlarged. The RBC glycogen content was 190 μg/g hemoglobin (controls 23-64 μg/g). A low carbohydrate diet, frequent meals, and avoidance of peak carbohydrate challenges resulted in a significant decrease in liver volume without affecting the hematological condition. Studies of carbohydrate metabolism showed normal responses to glucose, insulin, free fatty acids, and glucagon. There were low levels of lactic acid. The galactose tolerance test showed a low lactic acid response, normal galactose clearing, no glucose response, and a low free fatty acid response. The fructose tolerance test revealed a marked decrease in lactic acid and no glucose response, indicating diversion of fructose towards the glycolytic sequence below the deficient glucose phosphate isomerase step. These results exclude the presence of liver glycogenosis caused by deficiencies of glucose-6-phosphatase or branching and debranching enzymes and of the enzymes of the phosphorylase system. The glycogen storage in this patient was caused by an imbalance between carbohydrate intake and the metabolic capacity of the glycolytic sequences.

6416 HEPATORENAL SYNDROME: REVERSAL BY PERITONEOVENOUS SHUNT.

(Eng.) Fullen, W. D. (Univ. Cincinnati Medical Center, Cincinnati, OH 45267). *Surgery* 82(3):337-341; 1977.

The cases of two patients with hepatorenal syndrome who were treated by insertion of a peritoneovenous shunt are presented. The renal deficit was corrected rapidly in both cases. A 62-yr-old woman with a slow onset syndrome with urine output of 100-150 ml/day and urinary sodium excretion of 1 mEq/day responded with large volume urinary output and sodium excretion. She is alive with minimal ascites 18 months after shunt. A 53-yr-old man with severe nutritional cirrhosis, alcoholic hepatitis, and eventual massive necrosis was treated for bleeding esophageal varices by portacaval shunt. Postoperative massive ascites progressed to acute hepatorenal syndrome. Insertion of a peritoneovenous shunt reversed the renal deficit. He eventually died due to a hemorrhagic diathesis caused by massive hepatic necrosis. The advantages of the peritoneovenous shunt over other therapeutic methods include technical simplicity, both immediate and long-term effectiveness, and minimal operative stress and risk.

6417 LIVER DYSFUNCTION IN HYPERTENSION.

(Eng.) Ramsay, L. E. (Western Infirmary, Glasgow, Scotland). *Lancet* 2(8029):111-114; 1977.

Liver function tests were carried out routinely in 582 hypertensive patients. The tests were abnormal in 10.5% of all patients and in 15.8% of men and 6.2% of women. The patients studied appeared to be representative of the whole clinic population. Liver dysfunction was related to alcohol consumption, heavy body weight, male sex, young age, and higher diastolic blood pressure. It is suggested that alcohol and obesity were the principal causal factors and that fatty infiltration of the liver was the probable pathology. Liver dysfunction was unrelated to treatment. Alcohol use was found to be heavy in 12% of male patients attending the clinic. The possibility that alcohol abuse may have a causal role in hypertension needs further study.

6418 RESPIRATORY PROPERTIES OF PORTAL BLOOD IN PATIENTS WITH HEPATIC INSUFFICIENCY.

(Rus.) Sulima, S. Ya. (Dept. Faculty Surgery, Medical Inst., Ivano-Frankovsk, USSR). *Vestn. Khir.* (6):44-46; 1977.

Changes in the gaseous composition of the blood from the portal vein and femoral artery were studied in 48 patients with hepatic insufficiency due to diffuse peritonitis. Five patients developed peritonitis after acute appendicitis; 4 after perforating ulcer of the stomach and small intestine; 3 after ileus; 16 after acute cholecystitis; 12 after acute pancreatitis; 4 after traumatic lesions of the stomach, liver, or intestine; and 4 patients had postoperative peritonitis. Characteristic features of the initial phase of hepatic insufficiency were circulatory hypoxia, decreased oxygen level in the blood from the portal vein, and elevation of arterio-venous difference. During the relapse of hepatic insufficiency, the oxygen level in the portal blood showed further decrease (up to 5.7 ± 0.6%). After intrahepatic infusions of therapeutic agents via the umbilical vein, blood transfusions resulted in a stabilization of the oxygen capacity of the portal blood (19.1 ± 1.2%) and in an elevation of the oxygen level in arterial blood (up to 17.3 ± 1.2%) and in portal blood (up to 10.7 ± 1.1%). Treatment reduced lethality of peritonitis from 15.0% to 6.6%.

6419 OBSTRUCTIVE JAUNDICE AFTER BONE MARROW TRANSPLANTATION.

(Eng.) Lipshutz, G. R.; Katon, R. M.; Lee, T. G. (Univ. Oregon Health Sciences Center, Portland, OR). *Gastroenterology* 73(3): 565-569; 1977.

The case of a patient in whom obstructive jaundice occurring after bone marrow transplantation was attributed to extensive leukemic infiltration of the pancreas and bowel is presented. The patient, a 12-yr-old boy, presented with jaundice, dark urine, light-colored stool, and pruritus 7 months after a successful bone marrow transplant for acute lymphocytic leukemia had been carried out. At that time, he developed jaundice and skin lesions (diagnostic of graft-versus-host disease) that were successfully treated with prednisone. A bone marrow examination at the time the patient presented with jaundice showed active erythrocytic and granulocytic lines with no neoplastic cells; marrow cultures were negative. The patient subsequently developed abdominal pain, gastrointestinal bleeding, and perforation. Abdominal ultrasound, upper gastrointestinal series, and endoscopic biopsy revealed recurrent leukemia at the pancreatic head and descending duodenum. Radiation diminished the obstructive jaundice, although recurrent gastrointestinal hemorrhage, and finally perforation supervened. This case is unusual in that rampant gastrointestinal involvement was manifest at a time when leukemic cells were impossible to find by careful premortem bone marrow examination.

6420 HLA-FREQUENCIES IN INTERMITTENT ACUTE PORPHYRIA. (Eng.) Teuber, J.; Druschky, F.; Franzke, W.; Baenkler, H. W. (Krankenhausstrasse 12, D-8520 Erlangen, W. Germany). *Int. Arch. Allergy Appl. Immunol.* 54(5):473-474; 1977.

Tissue typing was carried out in 20 nonrelated patients with intermittent acute porphyria using the lymphocytotoxicity test in a two-step method. Compared to the normal German population, there was a significant ($p<0.05$) increase in the frequencies of histocompatibility antigen HLA-A1 (45% of patients with porphyria versus 28.1% of normal population), HLA-A10 (30% versus 11.2%), HLA-A29 (20% versus 4.7%), HLA-B13 (15% versus 6.2%), HLA-B14 (20% versus 5.0%), and HLA-B27 (15% versus 8.2%). There was a significant decrease in the frequencies of HLA-A2 (35% versus 51.5%), HLA-A3 (5% versus 30.2%), HLA-A9 (5% versus 20.5%), HLA-A11 (0% versus 9.8%), HLA-A28 (0% versus 7.1%), and HLA-BW15 (5% versus 14.4%). No conspicuous combination between particular HLA alleles was detected. Regarding the number of HLA differences, a relation between the patients due to an undiscovered common ancestor must be considered.

6421 SPONTANEOUS RUPTURE OF THE LIVER: AN UNUSUAL COMPLICATION OF SLE. (Eng.) Levitin, P. M.; Sweet, D.; Brunner, C. M.; Katholi, R. E.; Bolton, W. K. (Moses H. Cone Memorial Hosp., Greensboro, NC 27420). *Arthritis Rheum.* 20(2): 748-750; 1977.

The case of a patient with systemic lupus erythematosus (SLE) in whom spontaneous rupture of the liver occurred secondary to arteritis is presented. The patient, a 27-yr-old woman, developed intermittent abdominal pain, hypertension, ascites, elevated serum creatinine, proteinuria, and renal failure after the delivery of her fourth child. SLE had been diagnosed about 9 yr earlier, and she had responded to treatment with prednisone; the steroid was discontinued in 1970. The abdomen was initially nontender, tense with fluid, and without organomegaly. Four days later, the patient developed severe and constant abdominal pain, which radiated to her right shoulder. Generalized abdominal tenderness was detected. A stool specimen for occult blood was negative, whereas a nasogastric aspirate for blood was slightly positive. Paracentesis yielded serosanguineous fluid. At emergency laparotomy approximately 6 l of bloody ascitic fluid were aspirated from the peritoneal cavity. An extensive hemorrhaging stellate-type laceration was found in the right lobe. Histologic examination of a liver biopsy showed a portal triad artery cut tangentially, and the material in the wall of the blood vessel had the appearance of fibrinoid necrosis. Arteritis of a medium-sized artery was seen in a rectus muscle biopsy. The liver was packed with gauze placed between the liver and diaphragm and brought through a right upper quadrant stab incision. The patient developed postoperative complications and terminal melena and hematemesis. The autopsy specimen revealed arteritis with fibrinoid necrosis of the medium and small triad hepatic arteries; arteritis was also seen in the pancreas, adrenal gland, skeletal muscle, and spleen.

6422 AUTOIMMUNOLOGIC REACTIONS IN SYPHILIS AND THEIR CORRELATION WITH COMPLEMENT FIXATION REACTION AND LIVER FUNCTION TESTS. (Rus.) Davydova, R. Z.; Burshtein, Ch. I.; Abdullaev, A. Kh. (Uzbek Scientific Res. Dermatovenerologic Inst., USSR). *Vestn. Dermatol. Venerol.* (8):44-49; 1977.

The incidence of anti-organ antibodies was studied in 116 patients with contagious syphilis. The patients were divided into three groups: group 1 included 31 patients with primary syphilis; group 2 included 35 patients with the first incidence of secondary syphilis; and group 3 included 50 patients with secondary, recurrent syphilis. The incidence of antibodies against liver, heart, brain, and kidney antigens, assessed by the reaction of antiglobulin consumption (RAC), was more or less similar in all three groups and ranged from 67 to 70%. Treatment with penicillin and cobalt-containing drugs, with bismuth, or with ampicillin alone, resulted in a significant reduction in the incidence of antibodies against heart, kidneys, and brain tissue (positive reaction was observed in 35-44% of the cases), while antiliver antibodies were more resistant and were detected in 62.5% of the cases. The results of RAC with liver antigen and reaction of complement fixation (RCF) coincided in 73% of the patients before the treatment, compared to 60% after treatment. The patients with a positive RAC reaction had an almost twofold increase of turbidity in the thymol test; a correlation between the indices of RCA and the thymol test was detected only before the treatment.

6423 METHODS OF HEMOSTASIS IN LIVER SURGERY (LITERATURE REVIEW). (Rus.) Chalganov, A. I. (S. M. Kirov Military-Medical Acad., Leningrad, USSR). *Khirurgiia* (4):128-131; 1977.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

6435 INFLUENCE OF GESTATIONAL AGE AND CLINICAL STATUS ON BILIRUBIN-BINDING CAPACITY IN NEWBORN INFANTS: SEPHADEX G-25 GEL FILTRATION TECHNIQUE. (Eng.) Cashore, W. J.; Horwich, A.; Karotkin, E. H.; Oh, W. (50 Maude St., Providence, RI 02908). *Am. J. Dis. Child.* 131(8):898-901; 1977.

To determine the influence of gestational age and clinical condition on bilirubin-binding capacity, total bilirubin-binding capacity was measured by Sephadex G-25 gel filtration in 43 clinically well and 45 clinically ill (jaundiced) newborn infants between 26 and 41 weeks of gestation. In the well patients, bilirubin-binding capacity, serum albumin concentration, and the molar-binding ratio of bilirubin to albumin were directly related to gestational age. In the jaundiced patients, serum bilirubin-binding capacity and albumin concentration also correlated with gestational age; however, from 32 to 41 weeks of gestation, the mean values for the sick infants were significantly lower than for the well infants. In the jaundiced infants, the molar binding ratio of bilirubin to albumin was also lower than in the well patients and did not correlate with gestational age. The data are in agreement with previous clinical findings indicating an increased risk for low bilirubin kernicterus among immature infants and suggest that some critically ill term infants may be at risk for kernicterus at serum bilirubin levels below 20 mg/100 ml.

6436 DIFFERENTIAL DIAGNOSIS AND TREATMENT OF FUNCTIONAL UNCONJUGATED HYPERBILIRUBINEMIAS. (Rus.) Loginov, A. S.; Block, Yu. E. (Central Inst. Gastroenterology, Moscow, USSR). *Ter. Arkh.* 49(6):75-81; 1977.

Problems encountered in the differential diagnosis of nonconjugated bilirubinemias were studied in 109 patients. There were 37 patients with Gilbert's syndrome, 29 with posthepatitis hyperbilirubinemia, 1 with Crigler-Najjar syndrome, 6 with congenital microspherocytic hemolytic anemia, and 36 with organic lesions of liver and gallbladder (6 with adipose liver degeneration, 11 with cirrhosis, 4 with active chronic hepatitis, 3 with chronic persistent hepatitis, 3 with cholelithiasis, 7 with chronic noncalculous cholecystitis, and 2 with chronic recurrent pancreatitis). Characteristic clinical features of functional hyperbilirubinemias included mild hyperbilirubinemia. The level of total bilirubin ranged from 1.05 to 4.4 mg% in the patients with Gilbert's disease and from 1.05 to 3.7 mg% in the patients with posthepatitis bilirubinemia; in almost two-thirds of the patients with both forms of the hyperbilirubinemia, the level of total blood bilirubin did not exceed 2 mg%. A normal size of liver and spleen; normal functional liver indices; and psychasthenia, cholecystitis, and dispeptic syndromes were also included, while all patients with congenital microspherocytosis showed marked splenomegalia and liver enlargement. Treatment of functional hyperbilirubinemias consisted of phenobarbital (50 mg, t.i.d. for 2-3 weeks) for the patients with relatively high bilirubin level (>2 mg%), and psychotherapy for the patients with initial bilirubin level (<2 mg%).

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

6439 POSSIBILITIES OF DETECTION OF PRECLINICAL FORMS OF TOXIC HEPATITIS BY ASSESSMENT OF ACTIVITY OF OXIDASES OF MIXED LIVER FUNCTION. (Rus.) Popov, T. A.; Kaskevich, L. M. (All-Union Scientific Res. Inst. Pesticides, Plastics and Polymers, Kiev, USSR). *Vrach. Delo* (3):126-130; 1977.

Activity of the oxidases of mixed liver function (OMF) was assessed in 45 persons with an occupational exposure to the pesticide. At clinical examination, diagnosis of mild toxic hepatitis was made in 22 patients and of inflammatory changes and dyskinetic disturbances of the biliary duct in 9 patients. OMF assay, which consisted of assessment of aminopyrin (AP) metabolites in the daily urine after single loading with AP (7 mg/kg, p.o.), showed significant elevation of AP metabolite excretion, and thus, inhibition of OMF in 42 patients. Marked elevation of 4-aminoantipyrine, which was detected in 7 patients without clinical symptoms of liver lesion (12.2 ± 1.25%, compared to 4.22 ± 0.49% in controls), is indicative of significant strain of adaptation mechanisms in the liver. This confirms the hypothesis that adaptation is a preclinical stage of chronic intoxication.

6440 CHRONIC LIVER DISEASE AND ACETAMINOPHEN. (Eng.) Johnson, G. K.; Tolman, K. G. (Univ. Utah Coll. Medicine, Salt Lake City, UT 84132). *Ann. Intern. Med.* 87(3):302-304; 1977.

The case is presented of a 59-yr-old woman who developed acute and chronic liver disease after receiving therapeutic doses of acetaminophen (9 tablets daily, total dose 2,925 mg, for approximately 11 months); the patient then developed anorexia and easy fatigability. The only clinical findings were a tender liver and abnormal liver function tests. A liver biopsy showed disruption of the hepatic architecture, expansion of the portal tracts with acute and chronic inflammation, bile duct proliferation, piecemeal necrosis, and creeping fibrosis throughout the lobule. The pattern was typical of chronic aggressive hepatitis with cirrhosis. The liver function tests returned to normal 5 weeks after acetaminophen was discontinued. Rechallenge with acetaminophen (2,925 mg/day) induced abnormal function tests within 2 weeks. The patient has been followed for 2 yr since that challenge and remains asymptomatic; the liver function tests are normal. The liver disease in this patient was either caused by acetaminophen or an underlying liver disease was exacerbated by the analgesic; in either case, it appears that acetaminophen can aggravate liver disease in doses not generally believed to be hepatotoxic.

6441 CHRONIC EXCESSIVE ACETAMINOPHEN USE AND LIVER DAMAGE.

(Eng.) Barker, J. D., Jr.; de Carle, D. J.; Anuras, S. (Univ. Iowa Hosp. and Clinics, Iowa City, IA 52242). *Ann. Intern. Med.* 87(3):299-301; 1977.

Three cases of toxic hepatitis associated with the chronic ingestion of excessive doses of acetaminophen are reported. Each patient (1 man, 2 women, aged 50-67 yr) took approximately 5 to 8 g of acetaminophen daily during a period of several weeks. The transient elevations of serum hepatocellular enzyme concentrations and the histologic evidence of toxic hepatitis suggest that the liver damage was related to the use of acetaminophen. Alcohol abuse in one patient and negative nitrogen balance in another may have increased the susceptibility to acetaminophen toxicity. With the increasing popularity of acetaminophen for mild pain relief, hepatotoxicity from acute or chronic ingestion may be more common than previously recognized, especially in those patients with predisposing conditions.

6442 ASPIRIN-INDUCED HEPATOTOXICITY AND ITS EFFECT ON JUVENILE RHEUMATOID ARTHRITIS.

(Eng.) Bernstein, B. H.; Singsen, B. H.; King, K. K.; Hanson, V. (Dept. Pediatrics, Univ. Southern California, P.O. Box 54700, Los Angeles, CA 90054). *Am. J. Dis. Child.* 131(6):659-663; 1977.

The prevalence of hepatic disease in children receiving aspirin for juvenile rheumatoid arthritis (JRA), the relation of hepatic disease to aspirin dose and serum salicylate level, and the effect of hepatic disease on the activity of JRA was investigated in 102 children. Elevated SGOT levels were found in 60 of 102 children taking aspirin for JRA. Serial investigations of SGOT were performed in 46 of these patients, and at least one SGOT value was elevated (>39 IU/1) in 91%. A correlation was noted between the degree and prevalence of SGOT elevation, aspirin dose, and serum salicylate values; however, elevated SGOT was often found in children taking moderate aspirin doses and having serum salicylate levels <25 mg/100 ml. Younger children (below age 11 yr) and patients with systemic JRA received higher aspirin doses than older children and patients with polyarticular or pauciarticular JRA. Elevated SGOT was significantly more prevalent in younger children and patients with systemic JRA. SGOT values above 100 IU/1 were associated with a reduced ESR and, in some cases, reduction of the symptoms. Three children with SGOT values above 500 IU/1 had hepatic biopsies. Mononuclear cell infiltrates in the periportal areas and ballooning of hepatocytes with increased amounts of fat and glycogen were noted, but there were no signs of hepatocellular necrosis or cirrhosis. These data suggest that aspirin should be considered a potential hepatotoxin and that children with JRA receiving aspirin therapy should have periodic liver function studies.

6443 CHOLESTATIC JAUNDICE FOLLOWING AZATHIOPRINE THERAPY.

(Ger.) Freise, J.; May, B.; Schmidt, E. (Medizinischen Hochschule, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany). *Dtsch. Med. Wochenschr.* 101(33):1223-1226; 1976.

The case reports of two patients, a 41-yr-old man and a 36-yr-old woman, who developed severe cholestatic jaundice after receiving prednisolone (48 mg/day to less than 18 mg/day) and azathioprine (150 mg/day-200 mg/day) for chronic progressive hepatitis and Wegener's granulomatosis are presented. The most prominent clinical feature was reversible abnormal liver function involving both elimination and synthesis. After unsuccessful treatment with prednisolone for chronic aggressive hepatitis, the first patient received azathioprine (150 mg/day). The patient experienced severe itching, jaundice, darkened urine, steroid acne (face and thorax), and an inflamed liver. There was also an 18-fold increase in the serum bilirubin level (304 μM). After discontinuation of the azathioprine treatment and an increase in the prednisolone dose to 60 mg/day, the serum bilirubin level decreased to 53 μM, but there was a short-termed increase in the transaminase, the α-LDH, the alkaline phosphatase, and the α-glutamyl transpeptidase levels. Normal values were reestablished after 6-8 weeks of this increased treatment. Similar results were observed for the 36-yr-old woman with Wegener's granulomatosis, who had received 200 mg/day azathioprine and 30 mg/day prednisolone. A high serum bilirubin level of 618 μM was observed. Histologic examination of liver biopsy indicated an intrahepatic cholestasis. Following cessation of azathioprine therapy and an increase in steroid dose (60 mg/day), a decrease in bilirubin level was observed. Over longer periods of azathioprine treatment (indirect optional hepatotoxin), regular monitoring of blood counts and liver functions seems necessary.

6444 CHOLESTATIC JAUNDICE FOLLOWING CHLORPROPAMIDE SELF-POISONING.

(Eng.) Frier, B. M.; Stewart, W. K. (Ninewells Hosp. and Medical Sch., Univ. Dundee, Dundee DD2 1UB, Scotland). *Clin. Toxicol.* 11(1):13-17; 1977.

The case of a patient who survived a massive overdose of chlorpropamide and developed cholestatic jaundice as a delayed complication is presented. The patient, a 19-yr-old woman, ingested 150 100-mg chlorpropramide tablets, and gastric lavage 6 hr later produced no tablet return. The patient was treated with glucagon (1 mg, i.m., every 4 hr) and required parenteral glucose for 6 days until normoglycemia was maintained by normal feeding. Fourteen days after poisoning, she developed nausea, anorexia, and pruritus, and by 21 days she was frankly icteric with dark urine and pale stools. The serum bilirubin reached 113.4 μM and the alkaline phosphatase level was 22 King-Armstrong U/dl.

A liver biopsy confirmed cholestasis with ballooning of the hepatocytes around centrilobular areas. Liver function tests returned to normal within 4 weeks, and clinical improvement occurred without specific therapy.

6445 CHOLESTATIC LIVER DISEASE ASSOCIATED WITH DIPHENYLHYDANTOIN THERAPY: POSSIBLE PATHOGENIC IMPORTANCE OF ALTERED BILE SALT METABOLISM. (Eng.) Campbell, C. B.; McGuffie, C.; Weedon, A. P.; Powell, L. W. (Christchurch Clinical Sch., Christchurch, New Zealand). *Am. J. Dig. Dis.* 22 (3):255-262; 1977.

The case of a 10-yr-old boy who presented with a prolonged cholestatic liver disease 5 weeks after starting diphenylhydantoin therapy is presented. The initial phase of illness was characterized by hepatocellular damage with swollen liver cells and centrilobular cholestasis. Severe hyperlipoproteinemia with eruptive xanthomata developed within 3 weeks of his initial jaundice. The second phase of illness was characterized by portal tract inflammation, with bile ductular proliferation and chronic cholestasis gradually resolving over a period of 15 months. It is postulated that diphenylhydantoin sensitivity produced swollen hepatocytes with hypertrophy of the smooth endoplasmic reticulum, reducing hepatic sinusoidal blood flow and the clearance of secondary bile salts. A fall in clearance of lipoproteins, including the cholesterol precursor of primary bile acid synthesis, may have been responsible for a reduction in serum bile acid concentration. High levels of serum lithocholic acid, largely unsulfated presumably due to decreased hepatic uptake, may have produced the prolonged second phase of this illness, in which histological changes resembled those seen in experimental animals following lithocholic acid administration.

6446 ERYTHROMYCIN JAUNDICE: DIAGNOSIS BY AN IN VITRO CHALLENGE TEST. (Eng.) Cooksley, W. G. E.; Powell, L. W. (Royal Brisbane Hosp., Brisbane, 4029, Australia). *Aust. N.Z. J. Med.* 7(3):291-293; 1977.

Lymphocyte transformation tests were carried out in a patient who had suffered from erythromycin estolate-associated jaundice 2.5 yr earlier. The patient, a 51-yr-old woman, presented with jaundice, pale stools, dark urine, pruritus, fever, and a palpable liver. The serum total bilirubin was 17.1 mg/dl, and the alkaline phosphatase and transaminases were also raised. Percutaneous transhepatic cholangiography did not outline the biliary tree, and endoscopic retrograde cholangiography showed a possible filling defect in the common bile duct. At laparotomy, there was a single stone in an otherwise normal gallbladder and no evidence of extrahepatic biliary obstruction. A liver biopsy revealed marked central hepatic cholestasis with scattered necrotic hepatocytes and moderate mononuclear cell infiltration in the portal tracts; these features suggested drug-induced hepatitis. The patient's peripheral venous lymphocytes were cultured in the presence of 5 and 80 μg/ml erythromycin estolate, erythromycin stearate, or erythromycin base. Whereas the transformation indices in the patient were 7.3 and 2.35 using homologous and autologous serum, resp., at an erythromycin estolate concentration of 5 μg/ml, the mean transformation index in controls was 0.60 ± 0.31; at 80 μg/ml, the indices in the patient were 0.96 and 0.47 with homologous and autologous serum, and that in the controls was 0.41 ± 0.28. Evidence of blastogenesis was not seen using the same concentrations of erythromycin stearate or erythromycin base. This suggests that the patient was "sensitized" to erythromycin estolate without exposing her to the risk of *in vivo* challenge. The results provide evidence that erythromycin estolate jaundice is mediated by immunological mechanisms.

6447 HALOTHANE MACROPHAGE MIGRATION INHIBITION FACTOR TEST IN HALOTHANE-ASSOCIATED HEPATITIS. (Eng.) Price, C. D.; Gibbs, A. R.; Williams, W. J. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff, Wales). *J. Clin. Pathol.* 30(4):312-316; 1977.

As an index of delayed hypersensitivity, *in vitro* halothane macrophage migration inhibition factor tests (halothane-MIF tests) were carried out on peripheral blood lymphocytes from five patients with halothane hepatitis. Twenty-two subjects exposed to halothane, but with no evidence of jaundice; 5 healthy hospital anesthetists; 9 jaundiced subjects without halothane exposure; and 10 healthy subjects with no history of exposure to halothane were also tested. The halothane-MIF test was positive in four of the five patients with halothane-induced hepatitis; the negative result was in a patient on steroid treatment. The test was negative in all other subjects. The results suggest that the halothane-MIF test may be useful in the diagnosis of halothane-induced hepatitis and as a screening procedure for the identification of susceptible subjects.

6448 LIVER DAMAGE AND HYPOGLYCEMIA IN ACUTE IRON POISONING. (Eng.) deCastro, F. J.; Jaeger, R.; Gleason, W. A., Jr. (Cardinal Glennon Memorial Hosp., St. Louis, MO). *Clin. Toxicol.* 10(3):287-289; 1977.

The case of a 16-month-old boy who died of acute liver failure after ingesting approximately 15 g of ferrous sulfate (5 g of elemental iron) is presented. Two hours after ingesting the iron, the serum iron level was 5,000 μg%. Therapy consisted of nasogastric lavage with sodium bicarbonate alkalinized normal saline, deferoxamine (80 mg/kg for the first 24 hr and 50 mg/kg/day thereafter), three exchange transfusions, and aggressive supportive care to treat acidosis and shock. The patient survived 5 days. On the second day postingestion, the blood sugar was 13 mg%, and the liver enzymes and blood ammonia levels progressively increased from this time to his death. This patient did not die during one of the three phases of acute iron toxicity (i.e., hemorrhagic gastroenteritis, asymptomatic, and cardiovascular collapse); his death was due to severe progressive liver failure that was complicated by pancreatic damage. These complications will probably occur more frequently as aggressive care prevents earlier death in acute iron poisoning.

6449 THERAPEUTIC COMPARISON OF THIOL COMPOUNDS IN SEVERE PARACETAMOL POISONING. (Eng.)

Solomon, A. E.; Briggs, J. D.; Knepil, J.; Henry, D. A.; Winchester, J. F.; Birrell, R. (Scripps Clinic and Res. Foundation, 476 Prospect St., La Jolla, CA 92037). *Ann. Clin. Biochem.* 14(4): 200-202; 1977.

The value of cysteamine in preventing paracetamol-induced liver damage was compared with that of amino acid solutions containing methionine and/or cysteine in 12 patients. The blood concentrations of paracetamol ranged between 0.67 and 1.83 mM. Six patients received an initial dose of 2.0 g of cysteamine i.v. over 10 min followed by 3 x 400 mg doses in 500 ml of 5% glucose infused over periods of 4, 8, and 12 hr; the total dose was 3.2 g over 20 hr. Six patients received an amino acid solution (four with Aminosol 10% in 500 ml saline and two with Aminoplex-14 in 500 ml saline). Five hundred milliliters of the solution was given i.v. per 3 hr to a total dosage volume of 1-1.5 l. The two test groups were comparable in age, sex distribution, and blood paracetamol concentration. Four patients treated with the amino acid solution had taken large amounts of alcohol together with paracetamol. No patient developed severe liver damage. One patient treated with cysteamine had raised AL.T, and two in the amino acid-treated group had mild increases in AL.T. No side-effects were encountered in the amino acid-treated patients, but nausea, vomiting, muscle twitching, and social withdrawal occurred in all patients treated with cysteamine. Amino acid solutions should be used as a temporary measure in patients suspected of massive paracetamol overdose while awaiting estimation of blood paracetamol concentration.

6450 HEPATIC VENO-OCCLUSIVE DISEASE DUE TO PYRROLIZIDINE (SENECIO) POISONING IN ARIZONA. (Eng.)

Stillman, A. E.; Huxtable, R.; Consroe, P.; Kohnen, P.; Smith, S. (2122 N. Craycroft, Suite 2G, Tucson, AZ 85712). *Gastroenterology* 73(2):349-352; 1977.

The case of a 6-month-old Mexican-American girl with documented hepatic veno-occlusive disease due to the ingestion of pyrrolizidine alkaloids is presented. The patient had a distended abdomen and a prominent abdominal venous pattern; her liver span was 9 cm and she had a palpable spleen. The initial SGOT was 794 (normal <120 for an infant), bilirubin 0.5 mg/100 ml, and albumin 3.3 g/100 ml. Radiological examination indicated the presence of ascites and a right pleural effusion. A needle liver biopsy revealed normal hepatic architecture and intact hepatocytes; however, the sinusoids were markedly distended with mature RBC. The wedged hepatic vein pressure was 15 mm Hg and a free hepatic vein pressure was 8 mm Hg. It was then learned that the patient had been fed large quantities of tea prepared by infusion of a locally marketed herb known as gordolobo yerba. This was identified as *Senecio longilobus* that was found to contain large quantities of pyrrolizidine alkaloids. It was calculated that during the 2 weeks before admission, the patient received a total dose of 70-147 mg of combined alkaloid and nitrogen oxide derivative. The patient's abdominal girth decreased and her abdominal venous pattern disappeared after treatment with a diet containing p.o. sodium (100 mg/day) and furosemide (12 mg/day); however, the liver remained firm, with a 9-cm span, and a biopsy 2 months after the initial biopsy revealed extensive central, portal, and sinusoidal fibrosis. Electron photomicrographs showed collagen deposits and fibroblasts in the space of Disse. Mexican-American infants and children with "atypical hepatitis" should be suspected of pyrrolizidine alkaloid ingestion, and a liver biopsy should be carried out.

6451 LIVER DAMAGE FROM LONG-TERM METHYLTESTOSTERONE. (Eng.)

Westaby, D.; Paradinas, F. J.; Ogle, S. J.; Randell, J. B.; Murray-Lyon, I. M. (Charing Cross Hosp. and Medical Sch., London W6, England). *Lancet* 2(8032):261-263; 1977.

To assess the risk of liver damage from long-term treatment with methyltestosterone, 60 patients (42 female-to-male transsexuals and 18 impotent men) receiving long-term therapy with methyltestosterone (50 mg, 3 times/day) were investigated. Nineteen patients had abnormal liver function tests, and 33 of 52 had abnormal liver scans, particularly those who had been treated for more than a year. Liver biopsy specimens showed accumulation of hepatocytes in the liver cords and within the walls of centrilobular veins, and early peliosis hepatis. One patient had a hepatic adenoma. Of the androgens, only 17α-alkylated steroids seem to be implicated in the development of cholestatic jaundice, peliosis hepatis, and liver tumors.

6452 LIVER DAMAGE IN THE HEMOLYTIC UREMIC SYNDROME. (Eng.)

van Rhijn, A.; Donckerwolcke, R. A.; Kuijten, R. H.; van der Heiden, C. (Wilhelmina Children's Hosp., Nieuwe Gracht 137, Utrecht, Netherlands). *Helv. Paediatr. Acta* 32: 77-81; 1977.

Changes in liver function during the acute stage of the hemolytic uremic syndrome (HUS) were studied in 31 patients, and two case reports with enzyme studies that are indicative of liver involvement during the recovery stage of HUS are presented. All patients showed a marked increase in serum LDH (1,910 IU; normal, 78-241 IU) and moderate increases in SGOT and SGPT (54 and 45 IU, resp.; normal <15 IU). Alkaline phosphatase (AP) and 5'-nucleotidase (5'-ND) remained normal. The two children with HUS showed significant increases in SGOT (260 and 441 IU, resp.), SGPT (110 and 156 IU), LDH (1,224 and 825 IU), AP, 5'-ND, and α-glutamyltranspeptidase during the recovery stage (10 and 12 days after admission, resp.), without evidence of HUS recurrence, suggesting parenchymal liver damage. One patient also developed jaundice and hepatomegaly. Overall, 2/31 patients developed signs of liver damage, suggesting an affinity between the etiologic agent of HUS and the liver in both patients.

6453 ELECTRON MICROSCOPIC OBSERVATION OF THE LIVER IN PORTAL HYPERTENSION FOLLOWING CHRONIC EXPOSURE TO VINYL CHLORIDE MONOMER. (Eng.)

Kurokawa, S.; Inagaki, T.; Okuyama, S. (Nakatsugawa Municipal Hosp., Nakatsugawa City, Gifu Prefecture, 508, Japan). *Gastroenterol. Jpn.* 12(2):64-69; 1977.

Liver biopsy specimens from two patients with portal hypertension following chronic exposure to vinyl chloride monomer were studied histologically and ultrastructurally. Noncirrhotic portal hypertension accompanied by esophageal varices and splenomegaly were present in both patients. Histological examination showed hepatic fibrosis. Ultrastructurally, there were large amounts of small, electron-dense, myelin-like lamellar material and marked proliferation and vesiculation of the smooth endoplasmic reticulum in the hepatocyte cytoplasm. The widened Disse's spaces, where the sinusoidal lining cells were arranged in multilayers, were plugged by collagenous fiber bundles. This plugging may be involved in the development of portal hypertension.

6454 EMERGENCY EMBOLIZATION IN BLUNT HEPATIC TRAUMA. (Eng.)

Jander, H. P.; Laws, H.; Kogutt, M. S.; Mihas, A. A. (Univ. Alabama Medical Center, 619 S. Nineteenth St., Birmingham, AL 35233). *Am. J. Roentgenol.* 129(2):249-252; 1977.

The case of a patient in whom a traumatic liver tear was embolized with Gelfoam to stop an otherwise uncontrollable hemorrhage is described. The procedure was probably life saving in this patient. Transient elevated transaminase and bilirubin levels returned to normal 3 weeks after embolization. A repeat hepatic arteriogram 4 months after embolization demonstrated good revascularization of the right hepatic lobe from the left hepatic, left gastric, and gastroduodenal arteries. This case demonstrates the therapeutic value and safety of selective hepatic arterial branch embolization in massive life-threatening hemorrhage.

6455 LIVER FUNCTION IN MECHANICAL INJURIES (LITERATURE REVIEW). (Rus.)

Felitsyn, L. N. (S. M. Kirov Medical-Military Acad., Leningrad, USSR). *Vestn. Khir.* (6):135-139; 1977.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

6456 RECENT ADVANCES IN THE IDENTIFICATION OF HEPATITIS VIRUSES. (Eng.)

Dienstag, J. L.; Purcell, R. H. (Massachusetts General Hosp., Boston, MA 02114). *Postgrad. Med. J.* 53(621):364-373; 1977.

A review of the identification of hepatitis viruses is presented. The discovery of virus-related antigens has resulted in rapid progress in viral hepatitis research in the last decade. The hepatitis B virion has been tentatively identified as a DNA virus with an endogenous DNA polymerase, and new serological markers for type B hepatitis have been discovered. Hepatitis A antigen has been identified on a virus-like particle thought to be the hepatitis A virion. Progressively more sophisticated assays for hepatitis antigens and antibodies have been applied to the study of viral hepatitis epidemiology and biochemical-biophysical characterization of the agents. Most recently, knowledge gained from such studies has been exploited to develop a prototype noninfectious but immunogenic hepatitis B vaccine using hepatitis B surface antigen (HBsAg) purified in large quantities from chronic HBsAg carriers. Especially exciting is the prospect, suggested by serological studies of viral hepatitis, that hepatitis viruses besides hepatitis A and B viruses will be identified.

6457 SIGNIFICANCE OF SUSPECTED "CHRONIC AGGRESSIVE HEPATITIS" IN ACUTE HEPATITIS. (Eng.)

Fauerholdt, L.; Asnaes, S.; Ranek, L.; Schiodt, T.; Tygstrup, N. (Rigshospitalet 2152, 9 Blegdamsvej, DK-2100 Copenhagen, Denmark). *Gastroenterology* 73 (3):543-548; 1977.

The value of histologic criteria in determining the time at which the transition from acute to chronic aggressive hepatitis occurs was investigated. In 17 patients with acute viral hepatitis, observed during a period of 7 yr, a liver biopsy showed changes compatible with chronic aggressive hepatitis and superimposed acute hepatitis. Follow-up biopsies showed normal liver in 14 cases, chronic persistent hepatitis in 1, and cirrhosis in 2. In 12 cases, the initial biopsy, which showed changes suggestive of chronicity, was taken 1 month or later after onset of symptoms of acute hepatitis. The patients developing chronic liver disease showed no characteristic clinical, laboratory, or histological features at the time of the first biopsy. If the diagnosis of chronic active hepatitis is based on histological findings alone in patients with prolonged acute hepatitis, the incidence of this condition will be grossly overestimated. The transition from acute to chronic hepatitis cannot be recognized with any degree of certainty by presently available methods.

6458 VIGOROUS MEDICAL MANAGEMENT OF ACUTE FULMINANT HEPATITIS. (Eng.) Auslander, M. O.; Gitnick, G. L. (Center for the Health Sciences, 10833 LeConte Ave., Univ. California, Los Angeles, CA 90024). *Arch. Intern. Med.* 137(5):599-601; 1977.

The risk factors and the usefulness of vigorous medical management were studied in 20 patients with acute fulminant hepatic failure and stage II, III, or IV hepatic encephalopathy attributable to viral hepatitis. These patients were treated according to a protocol that directed aggressive medical management of fluid balance with electrolyte solutions, plasma, and blood; acid-base balance; coagulation defects with fresh frozen plasma; blood replacement as needed; dietary protein elimination; and p.o. administered neomycin sulfate. Eight patients survived. Seven of the 13 patients who were positive for the hepatitis B surface antigen (HBsAg) survived, while 1 of the 7 patients who were negative for HBsAg survived. The stage of encephalopathy on admission did not correlate with survival. Patients under 40 yr of age had a 43% survival rate, while those over 40 yr had a 33% survival rate. Conservative but vigorous medical management may improve survival in fulminant hepatic failure.

6459 A REVIEW OF LOBULAR, PORTAL, AND PERIPORTAL HEPATITIS: INTERPRETATION OF BIOPSY SPECIMENS WITHOUT CLINICAL DATA. (Eng.) Ludwig, J. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Hum. Pathol.* 8(3):269-276; 1977.

A compilation of clinical diagnoses that must be considered whenever a morphologic diagnosis of lobular, portal, or periportal hepatitis has been made is presented, along with histologic findings that may enable the pathologist to list the suspected clinical conditions in an order of likelihood. Lobular hepatitis without bridging or confluent necrosis is frequent in acute (self-limited) viral hepatitis, is usually mild in unresolved viral hepatitis, and may occur in chronic persistent hepatitis, chronic active hepatitis, drug-induced hepatitis, or extrahepatic diseases (where it is mild). Lobular hepatitis with bridging or confluent necrosis may occur in acute (self-limited) viral hepatitis or drug-induced hepatitis, is always present in fulminant viral hepatitis, is frequent in severe cases of chronic active hepatitis, and is treated as chronic active hepatitis in cases of unresolved viral hepatitis. Portal hepatitis without definite lobular changes is always present in chronic persistent hepatitis; is frequent in unresolved viral hepatitis, extrahepatic diseases, drug-induced hepatitis, and hepatitis associated with chronic inflammatory bowel disease; and may occur in remission in cases of chronic active hepatitis. Periportal hepatitis without definite centrilobular and midzonal changes occurs in drug addicts with acute (self-limited) viral hepatitis; is infrequent in unresolved viral hepatitis and extrahepatic diseases; may occur, but is mild, in cases of chronic persistent hepatitis; is always present in mild or moderately severe cases of chronic active hepatitis; is frequent in hepatitis associated with chronic inflammatory bowel disease; and may occur in drug-induced hepatitis.

6460 STUDIES OF THE AETIOLOGY OF NEONATAL HEPATITIS AND BILIARY ATRESIA. (Eng.) Danks, D. M.; Campbell, P. E.; Jack, I.; Rogers, J.; Smith, A. L. (Royal Children's Hosp. Res. Foundation, Flemington Rd., Parkville, Victoria 3052, Australia). *Arch. Dis. Child.* 52(5):360-367; 1977.

Etiological factors were sought prospectively in 55 infants with extrahepatic biliary atresia, in 105 with neonatal hepatitis, and in 11 with intrahepatic biliary atresia. In neonatal hepatitis, infective causes were shown in 22 infants, galactosemia was seen in 6, and α_1-antitrypsin deficiency was found in 8; familial occurrence was noted in 10 additional infants, and unrelated second diseases were present in 24 of the remaining 59 infants. The only clues to etiology in extrahepatic biliary atresia were a suspicion of time-space clusters, a deficiency of affected infants born to young primiparous women, and an unexpected number of spontaneous abortions in the histories given by the mothers. Genetic factors appeared to be important in intrahepatic biliary atresia, but are not reported in detail. Both neonatal hepatitis and extrahepatic biliary atresia are considered to have multiple causes. Recurrence risks in siblings are one in seven for neonatal hepatitis of unknown cause, negligible in extrahepatic biliary atresia, and usually one in two or one in four in intrahepatic biliary atresia, depending upon the family history.

6461 LIVER INVOLVEMENT IN THE SYNDROME OF MIXED CRYOGLOBULINEMIA. (Eng.) Levo, Y.; Gorevic, P. D.; Kassab, H. J.; Tobias, H.; Franklin, E. C. (New York Univ. Medical Center, 550 First Ave., New York, NY 10016). *Ann. Intern. Med.* 87(3):287-292; 1977.

Because of the suggestion that hepatitis B virus (HBV) may have a role in the pathogenesis of mixed cryoglobinemia, the incidence and nature of liver abnormalities were studied in 36 patients with mixed cryoglobulinemia in the absence of underlying infectious, connective tissue, or lymphoproliferative disorders. Clinical or biochemical evidence of liver dysfunction was present in 84%. Hepatomegaly was detected in 77%, splenomegaly in 54%, and abnormalities in bilirubin, alkaline phosphatase, or serum glutamic oxalacetic transaminase in 77%. Only four patients had overt liver disease. Of 15 biopsies from 12 patients, there was normal tissue structure in 2, minimal nonspecific changes in 1, portal fibrosis in 3, chronic persistent hepatitis in 1, chronic active hepatitis in 2, chronic active hepatitis with cirrhosis in 4, and postnecrotic cirrhosis in 2. These findings, together with the previously reported high incidence of serologic evidence of HBV infection, support the view that the syndrome of purpura, arthritis, and nephritis is often a consequence of immune-complex vasculitis secondary to HBV infection.

6462 MORPHOGENESIS OF LIVER CHANGES IN CHRONIC ACTIVE HEPATITIS.

(Rus.) Bezprozvannyi, B. K.; Aprosina, Z. G.; Semendiaeva, M. E.; Potekaeva, M. A. (Bureau Forensic Medical Examination, Moscow, USSR). *Ter. Arkh.* 48(9):25-36; 1976.

Literature on the etiology and histologic manifestations of chronic active hepatitis (CAH) is reviewed. The chief morphological manifestation of CAH is progressive proliferative reaction of mesenchymal cellular elements. Polymorphic infiltrates of portal tracts consist primarily of lymphocytes, large lymphoid cells, plasmacytic cells, and eosinophilic leukocytes. Changes in the liver parenchyma develop usually only during the relapse of disease and consist of piecemeal necroses and active regeneration of hepatocytes in the zone of active connective tissue. Differences in the relationship between reaction of organization and reaction of rejection in CAH dynamics yield the different outcomes of disease. A predominance of infiltrative processes leads to development of the portal cirrhosis; predominance of necrotic changes leads to postnecrotic cirrhosis. The most pronounced and acute manifestations of rejection reaction lead to extended necroses, *viz.*, acute (in acute viral hepatitis) or subacute (in chronic hepatitis) toxic liver dystrophy.

6463 CHANGE IN THE EXOCRINE FUNCTION OF THE PANCREAS IN INFECTIOUS HEPATITIS.

(Rus.) Golubenko, A. M. (Kiev Inst. Advanced Medical Studies, Kiev, USSR). *Vrach. Delo* (2):140-142; 1977.

To evaluate the exocrine pancreatic function in infectious hepatitis, serum and urine amylase and lipase and urine exopeptidase were assessed in 61 patients with infectious hepatitis and in 32 healthy controls. The patients included 19 with mild manifestations of disease, 32 with moderate manifestations, and 10 with severe manifestations. During relapse, all patients showed elevation of serum and urine amylase activity; during the recuperation, blood amylase in all patients and urine amylase in the patients with moderate infectious hepatitis decreased. In the patients with severe manifestations, urine amylase remained elevated. Blood lipase activity was elevated in patients with severe disease. Activity of urine exopeptidase was increased in all patients.

6464 URINARY ENZYMES IN VIRAL HEPATITIS.

(Eng.) Dart, G. C. (Fairfield Communicable Diseases Hosp., Fairfield, Victoria, 3078, Australia). *Clin. Chim. Acta* 78(3):499-501; 1977.

Urinary aspartate transaminase (AST), fructose monophosphatase (FMPase), fructose diphosphatase (FDPase), and gamma glutamyl transaminase (gamma-GT) were determined in specimens from patients with viral hepatitis, and these levels were compared with those in specimens from normal subjects. All assays were carried out concurrently on pre- and post-dialysis specimens to determine the possible effect of dialysis on assay accuracy and sensitivity. Dialysis had no significant effect on the urinary enzyme activity. The mean post-dialysis levels of AST, FMPase, FDPase, and gamma-GT in specimens from normal subjects were 11.7 ± 3.2, 1.6 ± 0.7, 3.4 ± 3.3, and 35.7 ± 13.9 Karmen U, resp. The mean post-dialysis levels of these enzymes in specimens from hepatitis patients were 14.7 ± 6.2, 2.2 ± 1.2, 2.6 ± 2.0, and 40.7 ± 17.3 Karmen U, resp. Although AST does show an apparent increase in hepatitis patients, the standard deviation is too large to allow a firm conclusion to be drawn.

6465 COMPARATIVE EFFICACY OF SERUM BILIRUBIN, ASPARAGINE- AND ALANINE-AMINOTRANSFERASE DETERMINATION, THYMOL AND ZINC TESTS, AND URINARY UROBILINOGEN CONTENT ASSESSMENT FOR DIAGNOSIS OF ANICTERIC FORMS OF VIRUS HEPATITIS.

(Pol.) Kowalczyk, C. (Dept. Lab. Diagnosis, Health Care Hosp., Leczyca, Poland). *Pol. Tyg. Lek.* 31(35):1537-1539; 1976.

The efficacy of various biochemical tests for the detection of an early form of viral hepatitis was evaluated in 15 patients who had had contact with viral hepatitis. The patients were examined within 1-3 days of developing jaundice. The patients had significantly increased activities of serum asparagine aminotransferase (76 U, compared to 4-40 U in controls) and alanine aminotransferase (149 U, compared to 4-30 U in controls), increased content of serum bilirubin (0.65 mg%, compared to 0.3 mg% in controls), increased index of thymol test (5.8 U, compared to 5 U in controls), decreased index of zinc test (2.7 U, compared to 10 U in controls), and elevated level of urobilinogen. It is concluded that these tests should be used in the differential diagnosis of anicteric forms of viral hepatitis.

6466 ASSESSMENT OF LIVER GLUCONEOGENESIS IN PATIENTS WITH ACUTE AND CHRONIC LIVER LESIONS BY BLOOD LACTATE TURNOVER ASSAY. (Pol.)

Przyjemski, J.; Wlasiuk, M.; Chrostowska, H. (Hosp. Internal Diseases, Gdansk, Poland). *Przegl. Lek.* 33(12):979-983; 1976.

Lactate turnover assay was employed for the evaluation of gluconeogenesis in 37 patients with acute infectious hepatitis, 24 patients with various chronic liver lesions (5 with chronic infectious hepatitis, 12 with chronic aggressive liver inflammation, 1 with chronic liver inflammation, and 6 with cirrhosis), and 9 healthy controls. The level of blood lactate was assessed immediately after administration of 0.12 mM/kg sodium lactate (SL) and 3, 6, 10, 15, 30, 45, and 60 min later. Within 15 min, SL could not be detected in the controls; SL was retained in amounts ranging from 0.13 to 0.19 mM in patients with acute hepatitis to 0.22 mM in the patients with chronic hepatitis. The results demonstrate that lactate elimination disturbances persist longer than changes in other tests used to assess liver function.

6467 INFECTIOUS HEPATITIS AND GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY. (Eng.)

Berry, E.; Melmed, R. N. (Hadassah Univ. Hosp., Jerusalem, Israel). *Isr. J. Med. Sci.* 13(6):600-603; 1977.

To determine the factors that enable a rapid diagnosis of combined infectious hepatitis and glucose-6-phosphate dehydrogenase (G6PD) deficiency, the clinical and biochemical findings in 14 patients were compared with those in 50 patients with uncomplicated hepatitis and those in 14 patients with fulminant hepatitis. Similarities with the latter group included persistence of fever, tachycardia, leukocytosis, and hyperbilirubinemia of greater than 340 μM (20 mg/dl). A rise in bilirubin values of more than 50 μM (3 mg/dl) per day in patients with viral hepatitis strongly suggested the presence of G6PD deficiency. Despite the severity of the illness, prothrombin activity was well maintained in G6PD-deficient patients.

6468 SERUM GLYCOPROTEIN LEVEL IN PATIENTS WITH ACUTE AND CHRONIC HEPATITIS. (Rus.)

Postovit, V. A.; Shcheglova, S. A.; Gundalakh, A. I. (S. P. Botkin Hosp. of Infectious Diseases, Leningrad, USSR). *Klin. Med. (Mosk.)* 54(7):82-87; 1976.

The content of serum glycoproteins was studied in 71 patients with acute viral hepatitis, 52 patients with chronic hepatitis, and 12 patients with cirrhosis. Sialic acids were assessed by diphenylamine (DPA) reaction and by reaction with acetous reagent. Levulose (fructose) was assessed by ammonium molibdate. According to all three reactions, the patients with acute and chronic hepatitis and cirrhosis had significantly decreased level of serum glycoproteins. Treatment with prednisone caused normalization of glycoprotein level in the patients with acute viral hepatitis.

6469 CHARACTERISTIC FEATURES OF PROTEIN SPECTRA AND SERUM CHOLINESTERASE AND PEROXIDASE ISOZYMES IN VIRAL HEPATITIS. (Rus.)

Kazanbiev, N. K.; Bakuev, M. M.; Sultanov, G. V. (Dagestan Medical Inst., Makhachkala, USSR). *Sov. Med.* (5): 23-27; 1977.

Protein spectra and serum cholinesterase (CE) and peroxidase (PO) isozymes were studied in 42 patients with viral hepatitis, 27 with chronic hepatitis, 21 with cirrhosis, and 30 practically healthy subjects. Disc electrophoretic assessment of blood proteins showed more or less uniform changes in the cathode macroglobulins in all patients, while the anode fractions showed significant variability. The prealbumin fraction in the patients with viral hepatitis was significantly reduced over that of healthy subjects; the patients with chronic hepatitis displayed a simultaneous decrease in albumin and prealbumin fractions. The patients with viral hepatitis showed a marked decrease of CE_2-CE_5 activities; quantitative distribution of CE isozymes showed direct correlation with the clinical stages of the disease. PO activity was mildly reduced in 4 patients with chronic hepatitis and in 6 patients with cirrhosis; enzyme activity was slightly elevated in 17 patients with chronic hepatitis and in 4 patients with cirrhosis (6 and 11 patients, resp., showed a normal range of PO activity). All patients with active viral hepatitis had a significant increase in the PO fraction and showed an additional slow fraction.

6470 AUSTRALIA ANTIGEN (HBsAg) IN SERUM AND LIVER TISSUE IN ACUTE AND CHRONIC LIVER LESIONS. (Pol.)

Sowa, J. (Clinic Infectious Diseases, Krakow Medical Inst., Krakow, Poland). *Pol. Tyg. Lek.* 31(40):1713-1715; 1976.

The diagnostic efficacy of the presence of Australia antigen (HBsAg) was studied in 100 patients with various liver lesions. The patients included 19 with acute viral hepatitis (group 1), 3 with subacute hepatitis (group 2), 16 with chronic persisting hepatitis (group 3), 42 with chronic active hepatitis (group 4), 7 with postnecrotic cirrhosis (group 5), and 13 with other liver diseases. Serum HBsAg was assessed by immunoelectroprecipitation or double diffusion assay, and HBsAg in the liver tissue was assessed by immunofluorescent electrophoresis. Serum HBsAg was detected in 22 patients and liver HBsAg in 24 patients. The incidence of serum HBsAg was greater among the patients with acute viral hepatitis (36.8%) than in the other groups (33.3% in group 2, 31.3% in group 3, 16.6% in group 4, and 29.0% in group 5), while the frequency of the liver HBsAg was greater in patients with postnecrotic cirrhosis (43.5%) than in other patients (27.3% in group 1, 25.0% in group 3, 26.2% in group 4, and 7.6% in group 6). The simultaneous presence of HBsAg in the serum and liver tissue was detected in 16.0% of the patients with acute viral hepatitis, compared to 9.5% of the patients with chronic active hepatitis.

6471 BIOCHEMICAL AND BIOPHYSICAL PROPERTIES OF HEPATITIS B CORE PARTICLES DERIVED FROM DANE PARTICLES AND INFECTED HEPATOCYTES.

(Eng.) Fields, H. A.; Hollinger, F. B.; Desmyter, J.; Melnick, J. L.; Dreesman, G. R. (Center for Disease Control, 4402 N. 7th St., Phoenix, AZ 85014). *Intervirology* 8(6):336-350; 1977.

Hepatitis B core antigen (HBcAg) was purified from Dane particles and from infected hepatocytes, and its biochemical and biophysical properties were studied. An identical isoelectric pH of 4.0 was determined for labeled preparations of both Dane-derived and liver-derived HBcAg. Unlabeled liver-derived HBcAg demonstrated a lower isoelectric pH of 3.7. Molecular weight determinations by Sepharose 4B column chromatography revealed that liver-derived HBcAg had a molecular weight of 8.5-9.0 x 10^6 daltons. The sedimentation coefficient of both Dane- and liver-derived HBcAg was found to be 124S. Polyacrylamide gel electrophoresis revealed that iodinated HBcAg derived from Dane particles was very similar in polypeptide structure to HBcAg derived from infected liver tissue. Twelve polypeptides were resolved from Dane core particles, and seven to nine were resolved from liver core particles. Several polypeptides in both preparations comigrated with iodinated hepatitis B surface antigen (HBsAg). However, three polypeptides (88,000, 79,000, and 59,000 daltons) were found in both Dane- and liver-derived HBcAg but not in HBsAg, which suggests that these polypeptides are HBcAg-specific. Endogenous DNA polymerase activity was observed in both Dane- and liver-derived core particles.

6472 SERODIAGNOSIS OF HEPATITIS B VIRUS INFECTION BY ANTIBODY TO CORE ANTIGEN.

(Eng.) Irwin, G. R.; Allen, R. G.; Segal, H. G.; Allen, A. M.; Putnak, J. R.; Cannon, H. G.; *et al.* (Walter Reed Army Inst. Res., Washington, DC 20012). *J. Infect. Dis.* 136(1):31-36; 1977.

A radioimmunoassay inhibition test was used to detect antibody to hepatitis B core antigen (anti-HBc) in a military population in which hepatitis B was endemic. Anti-HBc was found in 39% of acute hepatitis patients negative for hepatitis B surface antigen (HBsAg) and in 96% of HBsAg-positive patients. Persistence of antibody to HBsAg (anti-HBs) in convalescent-phase sera was significantly greater ($p<0.001$) in individuals with acute HBsAg-positive hepatitis B than in patients with clinical HBsAg-negative hepatitis B. The prevalence of anti-HBc in the absence of HBsAg, anti-HBs, and clinical disease was 3.2% in this military population. In longitudinal studies of hepatitis B infection, the presence of anti-HBc preceded the presence of anti-HBs and improved the ability to determine the onset of subclinical infection. Anti-HBc is a useful serologic marker for the study of the epidemiology of hepatitis B and improves the efficiency of detection of hepatitis B virus infection.

6473 HEPATITIS-B VIRUS IN BEDBUGS (Cimex hemipterus) FROM SENEGAL.

(Eng.) Wills, W.; London, W. T.; Werner, B. G.; Pourtaghva, M.; Larouze, B.; Millman, I.; *et al.* (Hopital Claude Bernard, Paris, France). *Lancet* 2(8031):217-219; 1977.

The presence of hepatitis B surface antigen (HBsAg) was studied in bedbugs (*Cimex hemipterus* [F]) collected on four separate occasions from bedding in the huts of village dwellers in Senegal, West Africa. HBsAg was detected in unengorged nymph and adult bedbugs in each of the first three collections. Three of 28 such specimens were HBsAg-positive in the first collection, and 3 of 17 specimens were positive in the second collection. In the third, six of nine were HBsAg-positive when the bed occupant was known to be HBsAg-positive. Two of these six positive insects did not contain human serum proteins. Bedbugs in the fourth collection were captured and kept alive without a blood meal for 30 days. Three of 89 of these samples were HBsAg-positive. These are the highest field infection-rates of hepatitis-B virus reported in any insect species. The bedbug must be considered a potential vector of hepatitis-B virus.

6474 IDENTIFICATION OF LYMPHOCYTES IN PERCUTANEOUS LIVER BIOPSY CORES: DIFFERENT T:B CELL RATIO IN HBsAg-POSITIVE AND -NEGATIVE HEPATITIS.

(Eng.) Miller, D. J.; Dwyer, J. M.; Klatskin, G. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 72 (6):1199-1203; 1977.

To study the nature of the immune response to hepatitis B virus (HBV), the lymphocytes infiltrating the liver were isolated and characterized as thymus-derived (T) or bone marrow-derived (B) cells in 20 patients with hepatitis B surface antigen (HBsAg)-positive acute and chronic hepatitis, 8 patients with HBsAg-negative chronic hepatitis with prior evidence of HBV infection, and 5 patients with HBsAg-negative chronic hepatitis without prior evidence of HBV infection. The predominant cell infiltrating the liver was shown to be a T cell in all categories; however, the ratio of T to B cells was significantly lower (1.96) in the patients without evidence for HBV infection than in the patients who were HBsAg-positive at (7.86), or before (8.85) the time of study. The significantly ($p<0.001$) higher number of B cells in the patients with chronic hepatitis of unknown etiology suggests that a different immunopathogenetic mechanism is operative in this group. A peripheral T lymphocytopenia was observed in patients with both antecedent and existent HBs-antigenemia, but not in the patients without evidence for HBV infection.

6475 LIVER HISTOLOGY IN 34 HBsAg LONG-TERM HEALTHY CARRIERS.

(Eng.) Piccinino, F.;

Sagnelli, E.; Manzillo, G.; Pasquale, G. (Clinica delle Malattie Infettive della 1° Facolta di Medicina della Universita di Napoli, Via Cotugno 1, I-80135 Napoli, Italy). *Acta Hepatogastroenterol. (Stuttg.)* 24(3):148-154; 1977.

Liver biopsy specimens of 34 long-term carriers of hepatitis B surface antigen (HBsAg) with normal liver function tests, discovered among family members of patients with HBsAg-positive liver diseases, were investigated histologically. Of these 34, 12 had normal liver tissue and 8 had mild nonspecific changes, such as focal Kupffer cell hyperplasia or mild lymphocytic infiltrates in the portal tracts. Two subjects showed multiple histioid granulomata scattered in normal liver parenchyma. Of the remaining 12 cases, 8 showed some areas of pin-head necrosis and mild portal tracts infiltration and 4 showed some areas of focal parenchymal infiltration associated with portal tracts inflammation. These histological changes are considered to be very mild lesions within the spectrum of hepatitis. None of the patients had histological evidence of chronic liver disease. It appears that normal liver function tests may be useful in excluding severe histological abnormalities.

6476 PREVALENCE OF HEPATITIS B SURFACE ANTIBODIES IN ETHNIC GROUPS OF A CANADIAN HOSPITAL STAFF POPULATION.

(Eng.) Leers, W. D. (Wellesley Hosp., Toronto, Ontario, Canada M4Y 1J3). *Infect. Immun.* 17(2):257-262; 1977.

The suggestion that ethnic and racial factors influence the prevalence of hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs) was investigated in hospital staff members. The staff members were categorized into four "risk groups" according to frequency of exposure to blood, patients' specimens, and patient care. Of the total 526 staff members studied, 51.5% were of North American origin, 25.9% came from Europe, and the rest came from Asia, the West Indies, Africa, and Australia. The prevalence of anti-HBs was lowest among North American staff members (8.1%) and highest among Asians (42.3%, $p \leq 0.05$). Low-risk administrative staff had the significantly lowest number of anti-HBs-positive members (6.1%), whereas low-risk dietary staff (29.6%) and hospital assistants (30.6%) had the significantly highest prevalence of anti-HBs staff members. In contrast, the high-risk group of laboratory workers and special nurses had only 16.1% of staff members with anti-HBs. The results show that ethnic background and socioeconomic conditions have to be considered when various risk groups are compared for the presence of anti-HBs. The frequency of exposure to blood and patients' specimens or patient care is not the only determining factor in the prevalence of anti-HBs in health workers.

6477 HEPATITIS-B SURFACE ANTIGEN (HBsAg) AND ANTIBODY (ANTI-HBs) PREVALENCE AMONG LABORATORY AND NONLABORATORY HOSPITAL PERSONNEL.

(Eng.) Wruble, L. D.; Masi, A. T.; Levinson, M. J.; Rightsell, W. A.; Bale, G. F.; Bertram, P.; *et al.* (Univ. Tennessee Coll. Medicine, 951 Court Ave., Room 335M, Memphis, TN 37163). *South. Med. J.* 70(9):1075-1079; 1977.

The incidence of hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs) was determined in 588 hospital laboratory workers and in nonlaboratory hospital workers (controls) matched for race and sex and adjusted for age. The combined prevalence of antigen-antibody positivity among white female technicians was 12% versus 0% of controls ($p<0.005$). The highest prevalence (18%) among laboratory workers was found in chemistry technicians, and significantly elevated frequencies also were noted in histocytologic, hematologic, and general laboratory technicians and blood collectors; this was not explained by a history of previous blood transfusions or hepatitis. Prevalence among pathologists (16%) was significantly greater ($p<0.05$) than among radiologists not routinely performing angiography (2%). Prevalence among black female housekeepers, both laboratory (25%) and nonlaboratory (36%), was the highest, and was significantly greater ($p<0.05$) than among black female technicians (10%). Positivity was not correlated with current residence census tract socioeconomic indicators in black or white women. The data emphasize the need for continued identification of risks and improved protection measures in hospital workers.

6478 THE EFFECT OF HEPATITIS B ON PLASMA CHOLESTEROL AND STEROL BALANCE.

(Eng.) Saudek, C. D. (New York Hosp.-Cornell Medical Center, 1300 York Ave., New York, NY 10021). *Am. J. Med.* 63(3):453-458; 1977.

Cholesterol metabolism was studied in a patient with hepatitis B throughout 29 days of the incubation period, the entire preicteric phase (49 days), and 15 days into the icteric phase. The patient, a 61-yr-old woman, was found to have developed increased transaminase levels 53 days after the infusion of clotting factor. Three weeks after the onset of elevated transaminases, the serum became positive for hepatitis B surface antigen. As hepatic inflammation developed, the plasma cholesterol concentration declined, reaching 56% of its baseline level before the onset of jaundice. Fecal bile acids diminished slightly, whereas fecal neutral steroids were unchanged. As jaundice developed, the plasma cholesterol level rose abruptly, and fecal bile acid excretion decreased markedly. This report suggests that plasma cholesterol is diminished by hepatitis prior to the development of icterus. Cholesterol synthesis is probably decreased.

6479 RATIONAL USE OF HEPATITIS B IMMUNE GLOBULIN.

(Eng.) Iwarson, S. (Ostra Sjukhuset, S-41685 Goteborg, Sweden). *Scand. J. Infect. Dis.* 9(2):67-69; 1977.

Data concerning specific hepatitis B immunoglobulin (HBIg) prophylaxis is reviewed. The introduction of high titer HBIg makes passive immunization against hepatitis B infection possible. HBIg seems to be valuable after well-documented accidental exposure to hepatitis B surface antigen and for regular prophylaxis among dialysis patients. In one study of "needle-stick" postexposure prophylaxis, the incidence of hepatitis after 6 months of observation was 6.8% in gamma globulin-treated staff members and 2.0% among staff members treated with HBIg ($p<0.05$). In one study on dialysis-associated hepatitis prevention, 9.0% of patients who received high-titer globulin developed hepatitis within 8 months of the start of the study, as compared with 33.3% among dialysis patients given standard gamma globulin ($p<0.01$). In both studies, however, the passage of time resulted in more cases of hepatitis among the HBIg-treated subjects, making the final incidence of hepatitis not significantly different from that among gamma globulin-treated subjects. Regular HBIg-prophylaxis among hospital staff is questioned because some controlled studies failed to show any superiority over standard gamma globulin. The value of HBIg-prophylaxis among contacts of hepatitis B patients should be further evaluated. Passive immunization will give protection only for a limited period of time, and the clinical evaluation of vaccines against hepatitis B is awaited with great interest.

6480 HEPATITIS B VACCINES. (Eng.) Zuckerman, A. J. (London Sch. Hygiene and Tropical Medicine, London, England). *Nature* 267(5612):578-579; 1977.

Experimental hepatitis B vaccines, including hepatitis B small particle vaccines, hepatitis B polypeptide vaccines, and synthetic hepatitis B vaccines, are reviewed. The foundations for the development of these vaccines were laid by the demonstration of the relative efficacy of diluted serum containing hepatitis B virus heated to 98 C for 1 min in preventing or modifying the infection in susceptible volunteers. The production of protective surface antibody by hepatitis B surface antigen is the basis for the preparation of experimental vaccines from purified 22-nm spherical surface antigen particles from the plasma of asymptomatic hepatitis B surface antigen carriers. The administration of this vaccine resulted in a marked difference in the incidence of hepatitis B infection in patients and staff of a hemodialysis unit in comparison with a group of patients and staff who had not received the vaccine. Attempts are also being made to prepare vaccines from the constituent polypeptides of the 22-nm spherical particles of the hepatitis B surface antigen. These vaccines would have an added margin of safety since they would be even less likely than the 22-nm particle subunit vaccines to contain infectious virus or contaminating host proteins. An extension of the use of polypeptide immunogens is the isolation and structural identification of a small surface antigen peptide. This peptide could conceivably be synthesized, function as a hapten, and, when coupled to a suitable carrier, may serve as a vaccine. The momentum towards the production of unconventional hepatitis B vaccines is being maintained, and it would be imprudent to speculate whether successful cultivation of hepatitis B virus in tissue culture, which will lead to the development of ordinary vaccines, will be achieved before a synthetic vaccine appears.

6481 SIMULTANEOUS INFECTION WITH TYPE A AND B HEPATITIS VIRUSES. (Eng.) Hindman, S. H.; Maynard, J. E.; Bradley, D. W.; Berquist, K. R.; Denes, A. E. (Center for Disease Control, 4402 N. 7th St., Phoenix, AZ 85014). *Am. J. Epidemiol.* 105(2):135-139; 1977.

The occurrence of a common source hepatitis A epidemic among the residents of a mental institution in which hepatitis B is hyperendemic provided an opportunity to observe concurrent infections with both agents. Nine hepatitis B surface antigen (HBsAg)-positive individuals developed hepatitis A infections, which was documented by hepatitis A antibody seroconversion in eight. The incidence of hepatitis A infections in susceptible HBsAg-positive persons (67%) did not differ from that in HBsAg-negative individuals (63%). The icteric to anicteric infection ratio in the HBsAg-positives (1:1.7) was similar to that in the negatives (1:2.1), and the clinical course in the antigen positives did not differ significantly from that of the antigen negatives. In addition to confirming previous reports that the viruses of hepatitis A and B are immunologically distinct, these results document that infection with either is independent of the other and that the morbidity from simultaneous infection is no greater than that caused by either alone.

6482 SERODIAGNOSIS OF VIRAL HEPATITIS A: DETECTION OF ACUTE-PHASE IMMUNOGLOBULIN M ANTI-HEPATITIS A VIRUS BY RADIOIMMUNOASSAY. (Eng.) Bradley, D. W.; Maynard, J. E.; Hindman, S. H.; Hornbeck, C. L.; Fields, H. A.; McCaustland, K. A.; Cook, E. H. (Center for Disease Control, Phoenix, AZ 85014). *J. Clin. Microbiol.* 5(5):521-530; 1977.

A modified micro solid-phase radioimmunoassay (RIA) for antibody to hepatitis A virus (anti-HAV) was developed, and its specificity and sensitivity were verified by examination of coded human and chimpanzee serum specimens. This double antibody procedure was performed by coating the surface of a polyvinyl microtiter plate "well" with 200 μl of a 1:1,000 dilution of a patient's test serum. Purified HAV and ^{125}I-labeled IgG anti-HAV were sequentially added to form an antibody sandwich. Radioimmunoassay of early acute-phase serum specimens from human cases of hepatitis A revealed the presence of anti-HAV activity. Differential examination by RIA of IgG and IgM fractions of acute-phase sera from experimentally infected chimpanzees demonstrated that IgM contained the bulk of the anti-HAV activity. A modification of the RIA procedure for anti-HAV (RIA-IgM blocking), incorporating an incubation step with anti-IgM (Mu chain specific), was further shown to differentiate acute- from convalescent-phase hepatitis A sera. This adapted RIA-IgM blocking procedure required less than 1 μl of a single acute-phase serum specimen for the diagnosis of viral hepatitis A.

6483 DISTRIBUTION OF ANTIBODY TO HEPATITIS A ANTIGEN IN A POPULATION OF COMMERCIAL PLASMA DONORS. (Eng.) Hall, W. T.; Mondon, F. K.; Madden, D. L.; DeSouza, D.; Kane, J. L. (Electro-Nucleonics Lab., Inc., Bethesda, MD 20014). *J. Clin. Microbiol.* 6(2):132-135; 1977.

Plasma samples from 245 regular plasma donors were tested for the presence of antibody to hepatitis A antigen. Antibody was detected at an immune adherence hemagglutination titer of 1:10 or greater in 91 of the 245 donors. The frequency of anti-hepatitis A was significantly ($p<0.01$) lower in the 18- to 29-yr-old group (30%) than in the 30- to 49-yr-old group (57%). No significant differences between whites and blacks or men and women were observed. Eighty percent of the donors were in the age range of 18-29 yr, whereas 48% of the higher-titered plasmas (≥1:1,000) were in the 30- to 49-yr age group. By preselection of donors, it is possible to produce an immune serum globulin with a specific anti-hepatitis A titer.

6484 ANTIBODY TO HEPATITIS A ANTIGEN IN CHILDREN. (Eng.) Stevens, C. E.; Cherubin, C. E.; Dienstag, J. L.; Purcell, R. H.; Szmuness, W. (New York Blood Center, 310 E. 67th St., New York, NY 10021). *J. Pediatr.* 91(3):436-438; 1977.

The prevalence of antibody to hepatitis A (anti-HA) was determined in two groups of urban children, using immune adherence hemagglutination to detect antibody. Among 106 children without liver disease, 21.7% had anti-HA-positive sera. Anti-HA prevalence in these children increased with increasing age, being present in 8.8% of children under 5 yr, in 24.2% of those 5-9 yr old, and in 30.8% of those 10 yr or older. Among the 97 children without hepatitis B virus marker (hepatitis B surface antigen or antibody), anti-HA was present in the sera of 17.5%, while anti-HA was present in 66.7% of the 9 children with hepatitis B virus marker ($p<0.01$). The second group of urban children consisted of 31 children who had resided in a ward in which an epidemic of hepatitis had occurred 1-2 months prior to blood sampling; this group also included 37 children who had resided in another ward in the same hospital. All but 1 of 31 children residing in the epidemic ward had anti-HA-positive sera. Only 1 of the 37 nonepidemic ward children was anti-HA-positive.

6485 HEMODIALYSIS-ASSOCIATED HEPATITIS IN THE UNITED STATES, 1974. (Eng.) Snydman, D. R.; Bregman, D.; Bryan, J. A. (Viral Diseases Div., Bureau Epidemiology, Center for Disease Control, Atlanta, GA 30333). *J. Infect. Dis.* 135(4):687-691; 1977.

A survey of 312 dialysis units that had dialyzed 15,382 patients for 1 month or more in 1974 revealed that 953 of the dialyzed patients had contracted serologically confirmed hepatitis B infection (attack rate, 6.2%). Of the patients with hepatitis B, 88.6% had become chronic carriers of hepatitis B surface antigen (HBsAg), i.e., HBsAg-positive for 3 months or longer. Only 90 of the 312 units had screened patients for anti-HBsAg, and 165 patients had been positive for anti-HBsAg in 1974. In all, 98% of the units had conducted periodic surveillance of the patient population for HBsAg, and 60% of these units had performed screening once a month. The overall attack rate of hepatitis B among staff members employed for longer than 1 month in a dialysis unit approximated the rate for patients (5.8%); however, the incidence of HBsAg-positive cases among staff was significantly lower than that in the patient population (5.2%, $p<0.01$). Dialysis units that separated HBsAg-positive from HBsAg-negative patients had significantly ($p<0.01$) lower rates of hepatitis B among both patients (9.4%) and staff (10.1%) than did units that did not separate patients (13.4% and 18.5% for patients and staff, resp.).

6486 PROGNOSIS OF BABIES WITH NEONATAL HEPATITIS. (Eng.) Danks, D. M.; Campbell, P. E.; Smith, A. L.; Rogers, J. (Royal Children's Hosp. Res. Foundation, Flemington Rd., Parkville, 3052, Victoria, Australia). *Arch. Dis. Child.* 52(5):368-372; 1977.

To evaluate the prognosis of neonatal hepatitis, 105 infants with this entity were studied carefully and followed for up to 11.5 yr. Ascertainment was complete for those with severe and persistent jaundice, but less complete for mild or anicteric cases. Prognosis was poor (40% death or cirrhosis) in infants with persistently acholic stools, but relatively good (<15% death or cirrhosis) in those with less persistent and less obstructive jaundice. The presence of second diseases (including α_1-antitrypsin deficiency or a family history of other affected children) seemed to play a part in determining poor prognosis. Twenty-two infants presented with acute fulminant illness (with or without jaundice) in the neonatal period. Cytomegalovirus infection carried a relatively good prognosis.

LIVER AND BILIARY TRACT

Chronic Hepatitis

6494 EARLY AND LONG-TERM RESULTS OF IMMUNOSUPPRESSIVE TREATMENT OF CHRONIC AGGRESSIVE HEPATITIS. (Pol.) Machalska, M.; Sawaryn, T.; Szymonski, K.; Karasinska, M. (Clinic Infectious Diseases, Inst. Internal Diseases, Katowice, Poland). *Pol. Tyg. Lek.* 32(30):1167-1170; 1977.

From 1970 to 1976, 56 patients with chronic aggressive hepatitis underwent treatment with azathioprine (150-200 mg/day) and prednisone (30-60 mg/day). The patients could be divided into two groups: group 1 consisted of 36 patients with aggressive infectious hepatitis, and group 2 included 20 patients with aggressive hepatitis with clinical manifestations of cirrhosis. The efficacy of treatment, assessed by the decrease of serum bilirubin, alanine and asparagine aminotransferases, and α-globulin content, was evaluated 2 months and within 1-5 yr of the beginning of treatment. Immunosuppressive therapy for 1-3 yr resulted in objective improvement in 39 patients: response to the treatment was observed in 83.3% of the patients in group 1 and 45.0% in group 2.

6495 GIANT MULTINUCLEATED HEPATOCYTES IN AN ADULT WITH CHRONIC ACTIVE HEPATITIS. (Eng.) Richey, J.; Rogers, S.; Van Thiel, D. H.; Lester, R. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Gastroenterology* 73(3):570-574; 1977.

The case of an adult with giant multinucleated cells occurring in chronic active hepatitis is presented. The patient, a 36-yr-old woman, presented with jaundice, dark urine, and weight loss. She received i.m. tetracycline for 10 days, followed by p.o. dehydrocholic acid for 7 days. Serum hepatitis B surface antigen or antibody, mitochondrial antibody, antinuclear factor, and alpha-fetoprotein were not detected. A liver biopsy revealed features of chronic active liver disease, including extensive portal inflammation, disruption of the limiting plate by the inflammatory infiltrate, focal periportal hepatocellular necrosis, and widespread lesser cellular changes, including cell ballooning. The most striking feature of the infiltrate was the presence of many multinucleated hepatocytes throughout the parenchyma. Seven to 12 nuclei were present in single hepatocytes which, with reticulin staining, were single cells rather than syncytial cells. Her symptoms resolved with prednisone (60-10 mg/day) and cyclophosphamide (50 mg/day), but a liver biopsy 8 months later revealed macronodular cirrhosis and areas of active inflammation. A third biopsy 7 months later showed cirrhosis without inflammation, necrosis, or giant cells.

6496 LYMPHOCYTE POPULATIONS IN LIVER BIOPSY SPECIMENS FROM PATIENTS WITH CHRONIC LIVER DISEASE. (Eng.) Sanchez-Tapias, J.; Thomas, H. C.; Sherlock, S. (Royal Free Hosp., Hampstead, London, England). *Gut* 18(6):472-475; 1977.

Rosetting techniques were used to identify lymphocytes obtained from liver biopsies as thymus-derived (T), "activated" T, or constant fragment (Fc)-receptor bearing cells to provide further evidence on the possible involvement of these cells in autoimmune, viral, and alcohol-related liver disease. "Activated" T lymphocytes were present in the liver in alcohol-induced hepatitis, chronic active hepatitis, and in primary biliary cirrhosis but not in inactive cirrhosis, chronic persistent hepatitis, extrahepatic or drug-induced cholestasis. A greater percentage of lymphocytes bore Fc-receptors in chronic active hepatitis than in alcohol-induced hepatitis or cholestatic liver disease. The concentration of "activated" T cells in the peripheral blood in all groups studied was within the normal range, suggesting that the "activated" T cells found in the liver were reacting to either native or foreign antigens within the liver. The data on Fc-receptor-bearing cells are consistent with the involvement of antibody assisted K cell-mediated cytotoxicity in chronic active hepatitis.

6497 INCIDENCE AND IMMUNOCHEMICAL FEATURES OF SERUM CRYOGLOBULIN IN CHRONIC LIVER DISEASE.

(Eng.) Jori, G. P.; Buonanno, G.; O'Onofrio, F.; Tirelli, A.; Gonnella, F.; Gentile, S. (Istituto di Patologia Medica, Piazza Miraglia, 80138 Napoli, Italy). *Gut* 18(3):245-249; 1977.

The frequency of essential cryoglobulinemia was studied in 150 patients with chronic liver diseases. Essential cryoglobulinemia was detected in 44 of the patients. Cryoglobulinemia prevailed in the patients whose hepatic tissue showed more features of active inflammation and in women. There were no correlations between cryoglobulinemia and either hepatitis B surface antigen positivity or alcoholic liver disease. Mixed cryoglobulins made of heterogeneous immunoglobulins without monotypic components were mostly associated with established cirrhosis, whereas monotypic cryoglobulins were exclusively found in patients with either persistent or aggressive chronic hepatitis. Mixed cryoglobulins with a monotypic component were associated with all histological grades of liver damage. These results afford an objective evaluation of both the frequency and immunochemical features of cryoglobulins associated with chronic inflammatory liver disease.

6498 IN VITRO STUDIES ON IgG-MEDIATED LYMPHOCYTE CYTOTOXICITY IN CHRONIC ACTIVE LIVER DISEASE.

(Eng.) Kawanishi, H. (Ann Arbor Veterans Admin. Hosp., Ann Arbor, MI 48105). *Gastroenterology* 73(3):549-555; 1977.

Antibody-dependent cytotoxicity mediated by allogeneic nonimmune lymphocytes (NL) was studied *in vitro* in sera from 10 patients with chronic active liver disease (CALD). NL in significant numbers adhered to the surface of target Chang monolayer cells pretreated with the sera of CALD patients (immune adherence of NL) and were cytotoxic. This phenomenon was blocked by anti-IgG and the constant fragment (Fc) of IgG. Test sera, absorbed with Chang cells or human adult liver tissues, failed to provoke target Chang cell lysis. Small amounts of granular-appearing IgG were demonstrated on the surface of Chang cells treated with the CALD sera from 8 of the 10 patients (membrane-fixed IgG). It is concluded that the antibody-dependent cellular cytotoxicity in this *in vitro* system is mediated by the IgG of CALD sera, most likely bound to target cell surface antigens, and that effector NL appear to lyse the target cells by direct contact through the Fc portion of the above membrane-fixed IgG. This immune cytotoxic process may play a role in the pathogenesis of CALD.

6499 HEPATITIS B ANTIGEN IN CHILDREN WITH CHRONIC HEPATITIS AND LIVER CIRRHOSIS.

(Ser.) Filipovic, D.; Popovic, E. (Serbian Inst. Maternity and Child Protection, Novi Beograd, Yugoslavia). *Srp. Arh. Celok. Lek.* 104(6):415-420; 1976.

The presence of hepatitis B antigen (HB Ag) was assessed in 71 children (10 months-15 yr) with chronic liver lesions. There were 41 children with histologically confirmed cirrhosis, 17 with chronic aggressive hepatitis, and 12 with chronic persisting hepatitis. HB Ag was detected in 10 patients with cirrhosis, 7 with chronic aggressive hepatitis, and 3 with chronic persisting hepatitis. Increased serum transaminase activity (up to 200 U/ml) was detected in 25 patients with cirrhosis, in 17 with aggressive hepatitis, and in only 2 with chronic persisting hepatitis. There was no difference in the severity of clinical manifestation of liver lesion between HB Ag-positive and -negative patients.

6500 AUTOIMMUNE COMPONENT IN PATIENTS WITH CHRONIC ACTIVE HEPATITIS AND ITS ASSOCIATION WITH DETECTION OF SURFACE HEPATITIS B ANTIGEN.

(Rus.) Nasonov, E. I.; Burlev, V. A.; Golosova, T. V.; Speransky, A. I.; Somova, A. V.; Podymova, S. D.; *et al.* (Inst. Hematology and Blood Transfusion, Moscow, USSR). *Ter. Arkh.* 49(6):84-89; 1977.

The results of comparative analysis of the incidence and titers of organospecific autoantibodies, rheumatoid factor (RF), concentration of Ig, and incidence of surface hepatitis B antigen (HBsAg) in 71 patients with chronic active hepatitis (CAH) are presented. Antibodies to the smooth muscles (SMA), mitochondrial antibodies (MA), and antinuclear factor (ANF) were assessed by nondirect immunofluorescence; RF was assessed by latex-agglutination; and IgG, IgA, and IgM were assessed by radial immunodiffusion. HBsAg was assessed by the reaction of precipitation in gel (RPG), reverse hemagglutination (HA), and by enzymoimmune assay (EIA). The patients could be divided into two groups. Group 1 included 35 HBsAg-negative patients, and group 2 included 36 HBsAg-positive patients. The patients in group 2 could be further subdivided into subgroup A, 19 patients in whom HBsAg was detected in all assays; subgroup B, 11 patients in whom HBsAg was detected in HA and EIA; and subgroup C, 6 patients in whom HBsAg was detected only in EIA. It was found that regardless of HBsAg detection, the patients with CAH had increased content of IgG and IgM, the presence of organospecific antibodies, and RF. The only exception comprised the patients in subgroup A, who showed dissociation between the high titer of HBsAg and immunologic manifestations of pathologic process.

6501 OBSERVATIONS ON THE COURSE OF HEPATITIS-B-ANTIGEN-POSITIVE CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Ger.) Schimmelpfennig, W.; Maluszek, S.; Wagner, K.; Geserick, G. (II Medizinische Klinik des Bereiches Medizin [Charite], Schumannstr. 20/21, 104 Berlin, W. Germany). *Dtsch. Gesundheitsw.* 32(2):62-64; 1977.

A retrospective study of liver morphology, liver function, and hepatitis B surface antigen (HBsAg) levels in 21 patients with HBsAg-positive chronic hepatitis is presented. Of the 21 patients, 1 had chronic persistent hepatitis, 12 had chronic aggressive hepatitis, 2 had chronic aggressive hepatitis with lesser activity, 1 had cirrhosis of the liver with portal hypertonia, 2 had cirrhosis of the liver without hypertonia, and 3 had cirrhosis of the liver with portasystemic shunt. Of the 21 patients, 6 died during the 1st month to 3.5 yr of examination. In seven cases (5/15 living patients and 2/6 deceased patients), migration electrophoresis indicated negative HBsAg results. Various therapy protocols applied to the 15 patients (azathioprine + prednisolone, prednisolone, azathioprine, tolbutamide) indicated that there was no correlation between therapy and antigenemia. Of the 10 HBsAg positive cases (10/15), there was only 1 case with a deteriorating result (chronic aggressive hepatitis becoming cirrhosis). A favorable development (chronic aggressive hepatitis becoming chronic persistent hepatitis) was seen in five cases. Of the five patients showing no HBsAg activity, three developed cirrhosis. Under immunosuppressive therapy, HBsAg-positive patients exhibited symptoms similar to HBsAg negative patients. Two conclusions on the prognosis of HBsAg positive patients are drawn: when there is an HBsAg persistence in acute hepatitis B, there is a subsequent transformation of the disease into the chronic form with an unfavorable prognosis and when an HBsAg persistence is observed for chronic hepatitis and cirrhosis, there may not necessarily be an increase in the severity of the disease.

6502 BIOCHEMICAL INDICES OF THE CHRONIC PROCESS ACTIVITY IN THE LIVER. (Rus.) Fedyanin, Yu. P. (Dept. Hosp. Therapy, Chita Medical Inst., Chita, USSR). *Klin. Med. (Mosk.)* 55(4):64-68; 1977.

6503 FUNCTIONAL CONDITION OF THE THYROID GLAND AND THYROTROPIC FUNCTION OF THE HYPOPHYSIS IN PATIENTS WITH CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Rus.) Shlimovich, P. B.; Zus, B. A.; Nikolaeva, A. A. (Dept. Hosp. Therapy, Leningrad Inst. Medicine and Hygiene, Leningrad, USSR). *Ter. Arkh.* 49(2):75-80; 1977.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

6504 ABNORMAL MITOCHONDRIA IN HEPATOCYTES IN HUMAN FATTY LIVER. (Eng.) Petersen, P. (Rigshospitalet, 2100 Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand. [A]* 85(3):413-420; 1977.

Light and electron microscopy of liver biopsies from 30 patients with fatty livers due to alcohol consumption, obesity, or diabetes (overt or latent) were compared with those of liver biopsies from 7 normal control patients. The frequency of hepatocytes containing abnormal mitochondria was significantly ($p<0.02$) higher in patients with fatty liver (16.4%, range 0.6-77.9%) than in controls (1.1%, range 0-3.0%). Hepatocytes containing abnormal mitochondria were found exclusively or predominantly in the periportal area of normal and fatty livers. In normal livers, the frequency of hepatocytes containing abnormal mitochondria was 3.3% (range, 0-7.7%) in the periportal area and 0% in the centrilobular area of the liver ($p<0.01$), while in fatty livers, the corresponding frequencies were 35.8% (range, 1.3-94.0%) and 1.0% (range 0-6.8%), resp. ($p<0.01$). In the periportal area of fatty livers, the frequency of hepatocytes with abnormal mitochondria was again significantly higher ($p<0.01$) than that for normal livers. The occurrence of abnormal mitochondria was not correlated with the degree of steatosis, and the increase in number of abnormal mitochondria was equally high in alcoholics, diabetics, and obese subjects. Electron microscopy of abnormal mitochondria revealed enlarged, irregularly shaped mitochondria that generally contained an increased amount of cristae and always contained paracrystalline inclusions, i.e., parallel-arranged bundles of filamentous-like formations. The higher the frequency of hepatocytes with abnormal mitochondria, the more frequent was the presence of paracrystalline inclusions in the mitochondria. The ultrastructural appearance of the abnormal mitochondria and the periportal localization of hepatocytes containing such mitochondria suggest a hyperfunctioning of mitochondria that may prevent the development of steatosis in these areas.

6505 AMYLASE, HEPATIC ENZYMES AND BILIRUBIN IN SERUM OF CHRONIC ALCOHOLICS. (Eng.)

Skude, G.; Wadstein, J. (Malmo General Hosp., Malmo, Sweden). *Acta. Med. Scand.* 201(1/2):53-58; 1977.

The serum concentration of bilirubin and the activities of aspartate aminotransferase (ASAT, GOT), alanine aminotransferase (ALAT, GPT), γ-glutamyltransferase (GT), total amylase, and pancreatic isoamylase were determined in sera of 182 male chronic alcoholics and 97 male controls. Twelve percent had abnormally high levels of bilirubin, 73% increased activity of S-ASAT, 50% increased S-ALAT, and 69% increased S-GT. The highest values were often found after 5-20 yr of well documented alcoholism. Some patients with alcoholism of more than 20 yr duration displayed a slight tendency towards normalization of the activities. For all parameters, the scatter around the mean was greater in the patients than in the controls. Patients who had had attacks of delirium showed slightly higher S-ASAT and S-ALAT than other alcoholics. Determination of S-ALAT and S-bilirubin did not add to the cases with abnormal laboratory tests, demonstrated by the combination of S-ASAT and S-GT. In 14 patients, the above mentioned parameters were within normal limits, even though severe alcoholism had lasted for many years. Isoamylase determination disclosed 20% to have decreased activity of pancreatic isoamylases in serum, whereas only 6% had low total serum amylase activity.

6506 COMPLICATIONS OF DIURESIS IN THE ALCOHOLIC PATIENT WITH ASCITES: A CONTROLLED TRIAL.

(Eng.) Gregory, P. B.; Broekelschen, P. H.; Hill, M. D.; Lipton, A. B.; Knauer, C. M.; Egger, M.; *et al.* (Stanford Univ. Medical Center, Stanford, CA 94305). *Gastroenterology* 73(3):534-538; 1977.

To determine whether complications arise from diuretic treatment, 43 patients with decompensated alcoholic liver disease and ascites of recent onset were randomized to salt and water restriction alone (controls) or to salt and water restriction plus diuretics (diuresis group). The two treatment groups were comparable in clinical findings and laboratory results. Seven patients in the control group and five patients in the diuresis group died during the acute illness. Weight loss was more marked in the patients given diuretics (24 ± 4 lbs lost versus 6 ± 2 lbs), and the disappearance of ascites was more common in those given diuretics (16/22 versus 4/21). A modest decrease in serum sodium, an increase in serum potassium, and readily reversible elevations of blood urea nitrogen were noted in the diuresis group. Eight patients in each treatment group developed either the hepatorenal syndrome, marked electrolyte abnormalities, or encephalopathy. Diuresis can be accomplished in these critically ill patients without serious complications that can be attributed to the diuretic treatment.

6507 ANTIBIOTIC CONCENTRATIONS IN ASCITIC FLUID OF PATIENTS WITH ASCITES AND BACTERIAL PERITONITIS.

(Eng.) Gerding, D. N.; Hall, W. H.; Scierl, E. A. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Ann. Intern. Med.* 86(6):708-713; 1977.

To determine the clinical adequacy of systemically administered antibiotics in peritonitis, 35 paired specimens of serum and ascitic fluid from 21 patients with peritonitis and ascites, most with spontaneous bacterial peritonitis and alcoholic cirrhosis, were assayed for antibiotic content after the patients had received i.v., i.m., or p.o. antibiotics. Antibiotics assayed and number of determinations were: gentamicin, 14; tobramycin, 7; ampicillin, 5; clindamycin, 3; penicillin G, 2; cephalothin, 2; chloramphenicol, 2; and cefazolin, 1. In 31 paired specimens, the ascitic fluid antibiotic concentration was about one-half or more of the simultaneous serum level, and in 17, assays exceeded 90% of the serum level. All antibiotics studied penetrated ascitic fluid equally well. Clinical response to antibiotic therapy was good in 12 of 16 patients with culture-proven bacterial peritonitis. Antibiotic levels in ascitic fluid exceeded the minimal inhibitory concentration of the infecting organisms in all but one patient who responded. Direct i.p. instillation of antibiotics does not appear to be necessary routinely; however, there may be an initial lag of several hours before antibiotic concentrations in ascites achieve therapeutic levels.

6508 THE EFFECT OF GLUCAGON ON PLASMA CYCLIC AMP AND GLUCOSE CONCENTRATIONS IN PATIENTS WITH ALCOHOLIC CIRRHOSIS.

(Eng.) Strange, R. C.; Mjos, O. D.; Henden, T.; Jynge, P. (Dept. Clinical Chemistry, Univ. Edinburgh, Edinburgh, Scotland). *Acta Med. Scand.* 202(1/2):87-88; 1977.

The possibility that differences in plasma cyclic AMP or glucose concentrations after the i.v. injection of glucagon can be used to differentiate patients with liver disease from those with a normal liver was investigated in four patients with well-compensated alcoholic cirrhosis and five matched healthy controls. Blood was collected before, during, and 30 min after the i.v. infusion of glucagon (100 ng/kg/min). The plasma glucose concentrations appeared to be higher in the cirrhotic patients, but they were not significantly different from those in the normal subjects at any time. Similarly, the plasma cyclic AMP concentrations were not significantly different in the two groups. The failure to discriminate between healthy controls and cirrhotic patients may partly be explained by the suggestion that diffusible cyclic AMP represents only a small percentage of the total hepatic content of the nucleotide even after enhancement of adenyl cyclase activity by glucagon.

6509 ELEVATED BASAL GROWTH HORMONE LEVELS AND GROWTH HORMONE RESPONSE TO TRH IN ALCOHOLIC PATIENTS WITH CIRRHOSIS.

(Eng.) Zanoboni, A.; Zanoboni-Muciaccia, W. (Istituto di Clinica Medica 4, Padiglione Litta, Universita di Milano, via F. Sforza, 35, 20122 Milano, Italy). *J. Endocrinol. Metab.* 45(3):576-578; 1977.

In an effort to clarify the hormonal derangement frequently seen in men with alcoholic liver disease, the basal plasma growth hormone (GH) level and GH responses after the administration of synthetic thyrotropin releasing hormone (TRH) were studied in nine male alcoholics with cirrhosis. Basal plasma GH levels were elevated in eight cirrhotic patients, the mean level being 8.4 ± 1.4 ng/ml; this level was significantly higher than that in five normal men (2.5 ± 0.9 ng/ml, $p<0.02$). The i.v. administration of TRH (400 µg over 30 min) produced a prompt increase in plasma GH levels, with peak values (13.1 ± 2.0 ng/ml) occurring between 10 and 30 min. The GH concentrations were significantly higher ($p<0.01$) than those of the normal subjects, whose plasma GH was not raised by TRH. The results show that alcoholic cirrhosis, like acromegaly, also induces a GH response to a nonspecific stimulus, TRH.

6510 PLATELET UPTAKE OF OCTOPAMINE AND NOREPINEPHRINE IN HEPATIC ENCEPHALOPATHY.

(Eng.) Morelli, A.; Frintzilas, M.; Zimmon, D. S. (Dept. Medicine, Univ. Perugia, Italy). *Gastroenterology* 73(3):560-564; 1977.

To explore platelets as a model of intracellular amine metabolism in liver disease, platelet uptake of octopamine (OA) was studied in controls and patients with hepatic encephalopathy (HE), and the influence of OA and plasma from patients with HE on platelet norepinephrine uptake was investigated. Normal platelets incubated at 37 C actively accumulated OA. The ratio of platelet OA concentration to plasma concentration was 30:1, and platelet OA uptake was inhibited at reduced temperature; these results suggest uptake by an active process. More than 90% of OA accumulated by platelets was recovered intact after 1 hr. Thrombin released 40% of platelet OA, suggesting sequestration within amine storage granules. OA inhibited the uptake of [^{3}H]norepinephrine by platelets, suggesting that these substances share the same transfer system. Platelets of patients with HE demonstrated decreased uptake of OA and norepinephrine. Inhibition of platelet OA uptake was proportional to the clinical stage of HE. Plasma from patients with HE inhibited norepinephrine uptake by normal platelets. These findings suggest that plasma OA and/or other amines are taken up by platelets where they are protected from degradation. The reduced uptake of OA and norepinephrine by platelets from patients with HE could result from uptake blockade by intraplatelet amines and/or inhibition of platelet amine uptake by plasma amines. The demonstration of altered platelet OA and norepinephrine metabolism in patients with encephalopathy suggest that this model may be useful for the study of intracellular amines in liver disease.

6511 LYMPHOCYTE CYTOTOXICITY IN ALCOHOLIC HEPATITIS.

(Eng.) Kakumu, S.; Leevy, C. M. (Coll. Medicine and Dentistry New Jersey, Newark, NJ 07103). *Gastroenterology* 72(4):594-597; 1977.

The cytotoxicity of peripheral lymphocytes was evaluated in 20 patients with alcoholic hepatitis, 16 alcoholics with a normal liver, 17 patients with fatty liver, 10 with alcoholic-cirrhosis, 9 with chronic active hepatitis, and 4 with rheumatoid arthritis. Lymphocyte cytotoxicity to Chang liver cells was investigated by a microcytotoxicity test, and that to autologous liver cells obtained by percutaneous liver biopsy was studied using a ^{51}Cr release assay. Lymphocytes from patients with alcoholic hepatitis were highly cytotoxic to Chang liver cells and autologous liver cells when compared to those with healthy livers ($p<0.001$). Cell-free supernatant fluid of lymphocytes from patients with alcoholic hepatitis incubated with purified alcoholic hyalin for 5 days was significantly cytotoxic to Chang liver cells ($p<0.01$), indicating that a cytotoxic factor is elaborated by sensitized lymphocytes. A significant reduction in cytotoxicity was noted with disappearance of clinical features or direct addition of a purified isolate of alcoholic hyalin or its preincubation with lymphocytes. Preincubation of sensitized lymphocytes with acetaldehyde increased cytotoxicity for autologous liver beyond that obtained by the combined effects of lymphocytes alone and acetaldehyde alone ($p<0.001$); this indicates that ethanol toxicity and hyperactivity of lymphocytes independently and collectively contribute to development of cirrhosis in patients with alcoholic hepatitis who continue to imbibe alcohol.

6512 ALCOHOLIC HYALIN, MICROFILAMENTS AND MICROTUBULES IN ALCOHOLIC HEPATITIS.

(Eng.) Petersen, P. (Rigshospitalet, 2100 Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand [A]* 85(3):384-394; 1977.

The morphological relationship between alcoholic hyalin fibrils and microfilaments and microtubules in liver parenchymal cells from six patients with biopsy-demonstrated alcoholic hepatitis was investigated using light and electron microscopy. Alcoholic hyalin consisted of light filaments and darker swollen filaments that sometimes formed an amorphous electron-dense core. A highly proliferated rough endoplasmic reticulum (RER), with dilated and frequently invaginated cisternae, surrounded the alcoholic hyalin. The Golgi apparatus was hypertrophied to a high degree. The mitochondria were polymorphous and contained enlarged dark granules in the matrix. Some microtubules were found adjacent to the alcoholic hyalin, occasionally penetrating the hyalin mass. In a few places, microfilaments were in close connection with the light filaments of alcoholic hyalin, and there seemed to be a direct transition between the two types of filaments. Liver cells with only minor alcoholic hyalin content contained a large number of microfilaments in close relationship to or intermingled with microtubules, especially in the region between the proliferated RER and a hypertrophied Golgi complex containing very low density lipoprotein-line particles. These ultrastructural changes in liver cells with a minor amount of alcoholic hyalin may be related to an early stage in the development of alcoholic hyalin. The abundance of microfilaments in liver cells containing very little alcoholic hyalin indicates an increased motility of hepatocytes, which possibly is part of the regenerative processes. The possibility that microfilaments disintegrate and accumulate in the alcoholic hyalin mass is suggested.

6513 ULTRASTRUCTURE OF ALCOHOLIC HYALIN AND FATE OF THE AFFECTED HEPATOCYTES. (Eng.)

Rumpelt, H. J. (Pathologisches Institut der Universitat Mainz, Langenbeckstr. 1, D-6500 Mainz, W. Germany). *Virchows Arch.* [*Cell Pathol.*] 23(4): 339-351; 1977.

In liver biopsy specimens, foci of satellitosis (foci of alcoholic hyalin containing hepatocytes surrounded by accumulated WBC) were studied ultrastructurally. Within satellitosis hepatocytes, morphologic variants of alcoholic hyalin similar to those described in nonsatellitosis liver cells were observed. They appeared as clusters of randomly oriented, smooth filaments of homogenous electron density; bundles of filaments aligned in parallel arrays and exhibiting irregular densities and indistinct boundaries; and masses of a strongly osmiophilic amorphous material, presumably lipidic in nature. The individual hyalin body was composed of one, two, or all three components in varying proportions; an uptake by cytosegresomes was never observed. The WBC of satellitosis foci, which were mostly polymorphonuclear without obvious alterations, had close contact to the central hepatocytes and sometimes covered large holes in the hepatocellular plasma membrane. In other cases, hepatocytes and neutrophils were both destroyed, and the hyalin bodies were unaltered within the sinusoids. Alcoholic hyalin may represent an inert proteinaceous storage material, deposited at the site of synthesis, which becomes superimposed by a lipid component. In cases of alcohol-induced hepatocellular lesions, those hepatocytes that produce hyalin bodies may have a special metabolic sensitivity to alcohol; this may result in hyalin synthesis and accumulation, or may, under special conditions, lead to plasma membrane destruction with secondary satellitosis formation.

6514 XENON-133 ACCUMULATION IN HEPATIC STEATOSIS. (Eng.)

Ahmad, M.; Witztum, K. F.; Fletcher, J. W.; Hendershott, L. R.; Klos, D.; George, E. A.; *et al.* (Veterans Admin. Hosp., St. Louis, MO 63125). *J. Nucl. Med.* 18(9):881-885; 1977.

To examine the suggestion that hepatic xenon accumulation might result from increased hepatic fat content, liver ^{133}Xe accumulation was studied in human subjects referred for pulmonary ventilation perfusion study and in paired rat littermates, one group with alcohol-induced fatty liver, and the control fed isocaloric glucose. Xenon accumulation was increased in fatty livers and paralleled the amount of liver fat in the animal experiments; alcohol induced a 23-206% increase in hepatic fat content, in comparison with the paired control littermates. During routine ventilation studies in 42 patients, hepatic xenon accumulation and retention were correlated with alcoholic drinking history and hepatic function studies. Of 15 patients without xenon accumulation, 1 had a drinking history. Hepatic xenon retention was graded visually on a scale of 0 to 4+; no activity discernible in the hepatic area at any time was graded 0, and activity comparable to the greatest intensity in the lung, in the liver at the end of the 10-min "washout phase" was graded 4+. Of 13 patients with 1+ hepatic xenon, 5 had a drinking history, 3 were diabetic, 2 were obese, and 2 had elevated lipid levels. Of six patients with 2+ hepatic xenon, four had a drinking history, one had no drinking history recorded, and one was diabetic; two had abnormal liver function studies. All five patients with 3+ hepatic xenon had a drinking history and abnormal liver function. Of three patients with 4+ hepatic xenon, two had a drinking history and abnormal liver function; the other was an obese diabetic. There was a parallel between the degree of hepatic xenon accumulation and the degree of suspected alcoholic fatty infiltration or diabetes determined from the clinical data. These results suggest the possible utility of hepatic radioxenon accumulation as a diagnostic test for fatty infiltration of the liver.

6515 BIOCHEMICAL BASIS OF THE EFFECT OF ALCOHOL.

LIVER AND BILIARY TRACT

Cirrhosis

6517 QUANTITATIVE A-SCAN ANALYSIS OF NORMAL AND CIRRHOTIC LIVER. (Eng.) Wells, P. N. T.; Mountford, R. A.; Halliwell, M.; Atkinson, P. *In: Proceedings of Seminar on Ultrasonic Tissue Characterization Held at the National Bureau of Standards, Gaithersburg, MD, May 28-30, 1975. National Bureau of Standards.* (Washington, DC):pp. 61-70; 1976.

The development of quantitative methods of analyzing ultrasonic liver scans, and the results of such scans in normal and cirrhotic liver, are reviewed. These methods are based on measurements of intrahepatic echo amplitudes or echo spacings. The echo amplitude tends to be increased in cirrhosis. Using a frequency of approximately 1-5 MHz, this tendency was confirmed by computer analysis of the measurements of 100 consecutive cycles of the ultrasonic echo wavetrains in each of 30 separate scans from each of 30 individuals with normal livers, and 13 patients with cirrhosis. These data were acquired manually. In cirrhotics, the mean echo amplitude was 6 decibels greater than in normals. Similar results were obtained with an automated system of data acquisition. The results are compatible with a model in which the observed structure is a random noise effect; the dimensions of the pulse determine the scale of the fluctuation which is observed. The echoes from cirrhotic liver, higher in amplitude but otherwise very similar to those from the normal liver, could be due to similar targets with greater characteristic impedance mismatches.

6518 PORTAL PRESSURE MEASUREMENTS DURING ARTERIAL VASOPRESSIN INFUSIONS. (Eng.) Nusbaum, M. (Graduate Hosp., Univ. Pennsylvania, Philadelphia, PA). *Chir. Gastroenterol.* 11(1):153-156; 1977.

Data concerning portal pressure during vasopressin infusion are reviewed. Data in 30 patients in whom direct portal or wedged hepatic vein pressure measurements were carried out before and during the intraarterial infusion of vasopressin demonstrate a variable change in portal pressure despite control of bleeding esophageal varices. Eight-six percent of nonbleeding patients showed a decrease in portal pressure during vasopressin infusion in the superior mesenteric artery, whereas only 50% showed a similar decrease during active variceal hemorrhage. In eight patients, there was no measured change in portal pressure with vasopressin infusion, despite cessation of hemorrhage in seven. A compensatory increase in hepatic artery flow and esophageal smooth muscle contraction produced by vasopressin may explain these results. Of 50 patients with esophageal varices managed by the intraarterial infusion of vasopressin, 24% developed significant complications.

6519 PRESENTATION AND COURSE OF ASYMPTOMATIC PRIMARY BILIARY CIRRHOSIS. (Eng.) Long, R. G.; Scheuer, P. J.; Sherlock, S. (Royal Free Hosp., Pond St., London, NW3 2QG, England). *Gastroenterology* 72(6):1204-1207; 1977.

The cases of twenty patients with asymptomatic primary biliary cirrhosis who have been followed 2-11 yr are described. In every patient, liver histology was diagnostic of, suggestive of, or compatible with the diagnosis. Eighteen patients had a positive serum mitochondrial antibody, 18 had raised serum IgM, and 17 had markedly raised serum alkaline phosphatase values. A mean of 4.5 yr after diagnosis, 10 patients had not developed hepatobiliary symptoms; 4 of these patients have survived 6-10 yr. Ten patients developed symptoms after a mean of 2.2 yr; seven are still alive, but three have died of liver failure. The development of symptoms could not be predicted by either serum biochemical tests or hepatic histology. It is concluded that the diagnosis of asymptomatic primary biliary cirrhosis is compatible with 10 or more asymptomatic years.

6520 JEJUNAL MICROFLORA IN PATIENTS WITH LIVER CIRRHOSIS. (Eng.) Portela-Gomes, G.; Pinto-Correia, J.; Dantas, R.; Pires, I. R.; Laranjeira, M. R.; Figueiredo, A. (Univ. Hosp. Santa Maria, Av. Prof. Egas Moniz, Lisbon 4, Portugal). *Arq. Gastroenterol.* 14(2):72-75; 1977.

The bacteriology of the jejunal fluid was studied in 10 patients with liver cirrhosis and 5 controls. Controls had no Gram-negative aerobic microorganisms, but Gram-positive aerobic bacteria were found in counts near 10^2/ml and anaerobes up to 10^7/ml. Gram-positive aerobic bacteria up to 10^3/ml were found in the cirrhotic patients, and Gram-negative aerobic organisms were found in one case. Eight cirrhotic patients showed several anaerobic bacteria, up to 10^6. There was no significant difference between the bacteriological data of patients with liver cirrhosis and control subjects.

6521 RADIOIMMUNOASSAY OF SERUM BILE ACID LEVELS IN BIOPSY-PROVED CIRRHOSIS. (Eng.) Dasher, C. A.; Hirschowitz, B. I.; Spenney, J. G.; Gibson, R. G.; Mihas, A. A. (Univ. Alabama Medical Center, Univ. Station, Birmingham, AL 35294). *South Med. J.* 70(8):968-969, 973; 1977.

Serum bile acid levels were determined by a radioimmunoassay for conjugates of cholic acid in 18 patients with biopsy-proved cirrhosis, and the results were compared with those of conventional liver function tests. Serum bile acid levels were abnormal in all 18 patients, whereas the results of the other tests were abnormal in only 50% to 72% of patients. In patients with a well established diagnosis of cirrhosis, serum bile acid levels are a more sensitive indicator of liver dysfunction than standard liver function tests.

6522 DEFICIENCY OF CARNITINE IN CACHECTIC CIRRHOTIC PATIENTS. (Eng.) Rudman, D.; Sewell, C. W.; Ansley, J. D. (Emory Univ. Hosp., Atlanta, GA 30322). *J. Clin. Invest.* 60(3):716-723; 1977.

Because protein deficiency is common in the hospital population, the possible occurrence of nosocomial carnitine deficiency was investigated. Fasting serum carnitine concentration was measured in 16 normal subjects and 247 hospital patients in 16 disease groups. The normal range of carnitine was 55-103 μM. Only the cirrhotic group showed significant ($p<0.05$) hypocarnitinemia. Fourteen of 36 hospitalized cirrhotics had subnormal values for serum carnitine. The creatinine/height index, midarm muscle circumference, and triceps skin-fold thickness indicated protein-calorie starvation in the 14 hypocarnitinemic liver patients. In six of the hypocarnitinemic cirrhotics (average serum level 50% of normal), spontaneous dietary intakes of carnitine, lysine, and methionine were only 5-15% as great as in six normocarnitinemic, healthy controls. When these six cirrhotic and six normal subjects were given the same lysine-rich (3,200-3,400 mg/day), methionine-rich (2,000-2,200 mg/day), and carnitine-free (<10 μmol/day) nutritional intake, the normals maintained normal serum carnitine levels and excreted 100 μmol/day. The cirrhotics' serum level fell to 25% of normal, and urinary excretion declined to 15 μmol/day. Seven hypocarnitinemic cirrhotics died. Postmortem concentrations of carnitine in liver, muscle, heart, kidney, and brain averaged only one-fourth to one-third those in corresponding tissues of eight normally nourished nonhepatic patients who died after an acute illness of a 1-3 day duration. These data show that carnitine depletion is common in patients hospitalized for advanced cirrhosis, and that it results from three factors: substandard intake of dietary carnitine, substandard intake of lysine and methionine (the precursors for endogenous carnitine synthesis), and loss of capacity to synthesize carnitine from lysine and methionine.

6523 BILE ACID CONCENTRATIONS IN SYSTEMIC AND PORTAL SERUM IN PRESUMABLY NORMAL MAN AND IN CHOLESTATIC AND CIRRHOTIC CONDITIONS. (Eng.) Lindblad, L.; Lundholm, K.; Schersten, T. (Dept. Surgery, Sahlgrenska sjukhuset, Univ. Goteborg, Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(4):395-400; 1977.

Total bile acid concentration was determined in systemic and portal serum and in liver tissue from patients with normal liver function (control group, 43 patients) and from patients with extrahepatic cholestasis (22 patients) and portal cirrhosis (13 patients). In five patients, in whom a portal catheter was inserted through the umbilical vein, the diurnal variation in systemic and portal serum bile acid concentration was studied. In control patients, the fasting systemic serum bile acid concentration was 4.8 ± 0.5 μM, and the portal concentration was 12.9 ± 1.5 μM. In extrahepatic cholestasis, the bile acid concentration was significantly higher in both systemic (42.9 ± 9.1 μM) and portal serum (47.8 ± 9.2 μM) than corresponding values in cirrhosis (21.0 ± 4.4 and 20.1 ± 3.6 μM, $p<0.001$ and $p<0.05$, resp.). The bile acid concentration gradient between systemic serum, portal serum, liver tissue, and hepatic bile was 1:3:80:2,600 in the patients with normal liver function. In both the cholestatic and cirrhotic conditions, the systemic and portal serum bile acid concentrations were equilibrated. The bile acid concentration increased postprandially in systemic and portal serum, but the gradient between these concentrations was unchanged. It is suggested that portal and systemic serum bile acid concentrations are determined by the intestinal absorption rate in subjects with normal liver function and by the hepatic and renal clearance capacity in cholestatic and cirrhotic conditions.

6524 ANTIHAEMOPHILIC FACTOR A ACTIVITY, F VIII-RELATED ANTIGEN AND VON WILLEBRAND FACTOR IN HEPATIC CIRRHOSIS. (Eng.) Baele, G.; Matthijs, E.; Barbier, F. (Dept. Internal Medicine, Akademisch Ziekenhuis, De Pintelaan 135, B-9000 Ghent, Belgium). *Acta Haematol. (Basel)* 57(5):290-297; 1977.

Antihemophilic factor A (F VIII) activity, F VIII-related antigen (F VIII RA), and von Willebrand factor were measured in 46 patients with hepatic cirrhosis and in 30 normal controls. All three parameters were significantly higher in patients with hepatic cirrhosis than in controls. The mean values of F VIII activity, F VIII RA, and von Willebrand factor were 3.35 U/ml, 5.42 U/ml, and 4.29 U/ml, resp., for cirrhotics and 0.88 U/ml, 0.80 U/ml, and 0.78 U/ml, resp., for controls. In cirrhotics, F VIII activity was significantly lower than F VIII RA ($p<0.001$). These increases were found in decompensated as well as in compensated hepatic cirrhosis; no differences in F VIII activity, F VIII RA, or von Willebrand factor were noted according to the etiology of the cirrhosis. A significant correlation between F VIII activity and F VIII RA was found in cirrhotics ($r=0.5$, $p<0.001$), as well as in controls ($r=0.458$, $p<0.02$). A linear relationship between F VIII RA and von Willebrand factor was found in both cirrhotics ($r=0.338$, $p<0.01$) and in controls ($r=0.719$, $p<0.01$). However, in both groups, no relationship between F VIII activity and von Willebrand factor was noted. Although the existence of a low-grade intravascular coagulation in hepatic cirrhosis may be postulated, more information about the metabolism of F VIII protein is needed before it can be proven.

6525 SERUM GLYCOPROTEINS IN THE LIVER DISEASES. IV. ALPHA-1 ACID GLYCOPROTEIN LEVEL IN LIVER CIRRHOSIS. (Eng.) Arima, T.; Motoyama, Y.; Yamamoto, T.; Nagata, K.; Kondo, T. (Okayama Univ. Medical Sch., Okayama, 700 Japan). *Gastroenterol. Jpn.* 12(2):43-46; 1977.

Circulating alpha-1 acid glycoprotein (AGP) level was determined by radioimmunoassay in 27 cirrhotic patients, 11 patients with chronic active hepatitis with sublobular necrosis, and 10 normal subjects. The AGP levels in liver cirrhosis (49.3 ± 14.5 mg/dl) and in chronic active hepatitis with sublobular necrosis (63.3 ± 25.8 mg/dl) were significantly lower than those in normal subjects (90.4 ± 12.5 mg/dl; $p < 0.001$ and $p < 0.02$ for cirrhosis and hepatitis, resp.). In liver cirrhosis, the serum AGP level correlated negatively with the serum albumin concentration ($r = -0.612$, $p < 0.01$).

6526 CIRCADIAN STUDY OF IMMUNOREACTIVE PROLACTIN IN PATIENTS WITH CIRRHOSIS OF THE LIVER.

(Eng.) Tarquini, B.; Gheri, R.; Anichini, P.; Neri, B.; Buricchi, L. (Istituto di Semeiotica Medica, Villa Monna Tessa, Viale Pieraccini 18, 50139 Firenze, Italy). *Gastroenterology* 73(1):116-119; 1977.

The pattern of immunoreactive prolactin secretion over 24 hr in 7 patients with liver cirrhosis was studied and compared to that of 21 healthy controls. The results were analyzed by use of chronograms and by mean cosinor. Although the daily mean average secretion of serum prolactin by the cirrhotics was not different from that of the control subjects utilizing the standard *t*-test, cosinor analysis of the data failed to demonstrate a circadian rhythm for prolactin secretion in the cirrhotics. This loss of circadian rhythm provides a possible mechanism for the loss of the circadian rhythm of sodium excretion in cirrhotic patients. In addition, the observed prolactin dischronia may account for some other clinical observations (gynecomastia, hypogonadism, fluid balance problems) frequently observed in patients with advanced liver diseases.

6527 SPIRONOLACTONE METABOLISM IN NORMAL SUBJECTS AND IN PATIENTS WITH LIVER CIRRHOSIS.

(Eng.) Varadi, A.; Feher, T.; Bodrogi, L.; Koref, O. (Semmelweis Univ. Medical Sch., Koranyi S. u. 2/A, H-1083 Budapest, Hungary). *Arzneim. Forsch.* 27(8):1618-1620; 1977.

The dynamic excretion of aldadiene, the principal metabolite of spironolactone with biological activity, was studied in 37 controls and in 9 patients with liver cirrhosis following the administration of spironolactone. Aldadiene appeared in the 3-day urine collection, at approximately 3% of the dose. There was no significant difference in the biological half-life, calculated from the urinary pattern, and in the rate of excretion in patients with hepatopathy and the 22 hospitalized controls. Fifteen nonhospitalized controls exhibited the most rapid elimination of the metabolite. Increasing the spironolactone dose from 50 mg to 200 mg enhanced the percent rate of aldadiene excretion, while the biological half-life did not change. Spironolactone decreased the rate of dehydroepiandrosterone and androsterone excretion, even after a single dose. Determination of total 17-ketosteroids is of no value in the evaluation of adrenal function during spironolactone therapy, because the spironolactone metabolites were positive in the Zimmermann test.

6528 ARTHRITIS AND PRIMARY BILIARY CIRRHOSIS.

(Eng.) Child, D. L.; Mathews, J. A.; Thompson, R. P. H. (St. Thomas' Hosp., London SE1 7EH, England). *Br. Med. J.* 2(6086):557; 1977.

The cases of five patients with appreciable arthritic lesions and circulating rheumatoid factor in association with primary biliary cirrhosis are presented. The severity of the arthritic symptoms of the patients and the histological evidence for primary biliary cirrhosis varied, and the two aspects were generally inversely related. Serological results were positive for rheumatoid factor in all patients, and two patients fulfilled the criteria for "definite" rheumatoid arthritis. One of these two patients had severe systemic involvement compatible with rheumatoid disease; articular erosions and nodules were present in the other patient and in an additional patient. Only one of the five patients had hypercholesterolemia. The joint fluid from this patient contained free cholesterol crystals. There were periportal granulomatous changes in the liver biopsy specimens from two patients, and that from a third patient showed abnormal proliferating bile ductules.

6529 DIAGNOSTIC ASPECTS OF NEONATAL ASCITES: REPORT OF 27 CASES.

(Eng.) Griscom, N. T.; Colodny, A. H.; Rosenbert, H. K.; Fliegel, C. P.; Hardy, B. E. (Children's Hosp. Medical Center, Boston, MA 02115). *Am. J. Roentgenol.* 128(6):961-970; 1977.

Data from 27 live-born neonates with ascites were reviewed to analyze the causes and frequency of neonatal ascites. Seven neonates presented with urinary ascites, five had bowel disease, three had cardiac arrhythmias, two had liver disease, and one each had toxoplasmosis, ovarian cyst, and chylous ascites. Ileal perforation was identified as the cause of neonatal ascites in four infants, one infant had ileal atresia, and another had ileal volvulous and cystic fibrosis. Ileal duplication and perforation were found in one infant, and ileal perforation of uncertain origin was present in another infant. There was one case each of ascites caused by intestinal malrotation, volvulus, and ischemia; familial cirrhosis; and probable hepatitis. A protocol for the differential diagnosis of neonata ascites is presented that includes a physical examination, a planned sequence of radiological examinations, and paracentesis for fluid analysis.

6530 DETECTION OF ENDOTOXIN IN PLASMA AND ASCITIC FLUID OF PATIENTS WITH CIRRHOSIS: ITS CLINICAL SIGNIFICANCE.

(Eng.) Tarao, K.; So, K.; Moroi, T.; Ikeuchi, T.; Suyama, T.; Endo, O.; Fukushima, K. (Dept. Internal Medicine, Yokohama City Univ., 1197 Tomioka-machi, Kanazawa-ku, Yokohama 236, Japan). *Gastroenterology* 73(3):539-542; 1977.

Because of the frequency with which endotoxemia occurs in chronic liver disease, endotoxin was measured by the Limulus assay in plasma and ascites in 46 patients with cirrhosis having demonstrable esophageal varices (29/46 had ascites). The assay was positive in ascitic fluid in 23 of the cirrhotic patients with ascites. In plasma, a positive test was obtained in 22 in the group with ascites and in only 4 without ascites ($p < 0.01$). Of the 23 positive ascites specimens, 17 showed high titers ($\geq 10^{-3}$ μg/ml) of endotoxins. Hepatic uptake of ^{198}Au colloid was markedly reduced in 11 of the 17 patients with endotoxemia who were studied by scanning. Death occurred within 6 months in 47.8% of the patients with a positive endotoxin test, whereas only 16.7% of those with a negative test died in the same period ($p < 0.05$). No hypotension was noted in patients with toxemia and only two ran a fever above 37.5 C. Development of tolerance to endotoxin is suspected. A follow-up study has demonstrated sustained endotoxemia in some of these patients.

6531 CLINICAL EXPERIENCE WITH AUTOGENOUS ASCITIC FLUID INFUSION FOR CIRRHOTIC ASCITES. (Eng.) Graziano, J. L.; Reinhardt, G. F.; Howell, H. S.; Hacker, L. C.; Stanley, M. M. (Veterans Admin. Hosp., Hines, IL 60141). *Am. Surg.* 43(8):520-523; 1977.

Experience with autogenous ascitic fluid infusion in the treatment of 24 cirrhotic patients with intractable massive ascites is reported. All patients were men (aged 41-66 yr) diagnosed as having advanced nutritional cirrhosis, disabling ascites, and oliguria. An outflow catheter is placed through the abdominal wall lateral to the rectus sheath below the level of the umbilicus. This outflow catheter is then allowed to drain the ascites into a system of paired, closed sterile bags that are alternately used to infuse the ascites into a central vein. Infusion of ascites is continued at rates ranging from 250-1,000 ml/hr, depending upon the patient's tolerance to infusion. The average volume of ascites infused in the 24 patients was 18.4 l, and the duration of infusion averaged 3.8 days. The effects of ascitic infusion were well tolerated, and there was no mortality either during the infusion or during the subsequent 2-week interval. The average postinfusion weight loss was 11.4 kg. The average abdominal girth decreased 11.2 cm following infusion. The central venous pressure increased an average of 5.9 cm H_2O, and the urinary output during infusion averaged 10.9 l. The hematocrit dropped an average of 2.5%, the serum sodium decreased 0.4 mEq/l, and the serum urea decreased 1.9 mg/100 ml. The serum bilirubin level did not change, but the serum ammonia dropped an average of 21.3 μg/100 ml. Among 18 patients who were nonoperative candidates, 10 died 6 months after infusion due to complications of advanced liver disease. Of the eight others, four were free of ascites during this period. Among five patients who underwent portal decompressive surgery, all were alive 6 months after infusion without evidence of clinical ascites. The remaining operative patient died of hepatoma. Autogenous ascitic fluid infusion, using an alternating bag technique, is a safe and practical method to treat patients with advanced liver cirrhosis complicated by massive ascites.

6532 RENAL FAILURE ASSOCIATED WITH DEMECLOCYCLINE IN CIRRHOSIS. (Eng.) Carrilho, F.; Bosch, J.; Arroyo, V.; Mas, A.; Viver, J.; Rodes, J. (Hospital Clinico y Provincial, Casanova 143, Barcelona-11, Spain). *Ann. Intern. Med.* 87(2):195-197; 1977.

The effects of demeclocycline on renal function were studied in three patients with cirrhosis, ascites, and dilutional hyponatremia. The patients were treated with demeclocycline (600-900 mg/day, 8-9 days, p.o.) in an attempt to correct abnormal water retention. Demeclocycline administration resulted in (a) increased blood urea nitrogen and plasma creatinine concentrations, (b) reduction of inulin clearance by 63-78% and of para-aminohippurate clearance by 36-77%, and (c) an impairment of the renal concentrating ability. Urine osmolality decreased to hypotonic levels, but polyuria did not appear, probably because it was prevented by the reduction of the glomerular filtration rate. Renal failure was reversible when demeclocycline was withdrawn. No causes other than demeclocycline administration could be found to explain the reduction of the glomerular filtration rate and the estimated renal plasma flow.

6533 FAMILIAL PORTAL HYPERTENSION. (Pol.) Gacyk, W.; Celinska, W.; Klimkiewicz, E.; Dybicki, J. (Clinic General Surgery, Gdansk Inst. Surgery, Gdansk, Poland). *Wiad. Lek.* 30(12):969-971; 1977.

A case history of a deaf-mute girl with portal hypertension is presented. Although the patient had repeated hemorrhage from the esophageal varicose nodes and enlarged spleen and liver, she did not show the symptoms of liver dysfunction. Two brothers of the patient died of hemorrhage from the varicose nodes, and the third brother has enlarged liver and spleen. The patient underwent central splenorenal anastomosis, and 3 yr later was in good health and hemorrhage-free.

6534 LIGATION OF THE SPLENIC ARTERY IN PORTAL HYPERTENSION. (Rus.) Sazonov, A. M.; Ender, L. A.; Rodimin, V. V. (Dept. Clinical Surgery, Moscow Oblast Scientific Res. Clinical Inst., Moscow, USSR). *Khirurgiia (Mosk.)* (3):54-58; 1977.

The results of splenic artery ligation in 24 patients with portal hypertension syndrome are presented. Included were 12 patients resistant to the conservative treatment for ascites, 10 with hemorrhage from varicose esophageal veins, and 2 patients with varicose esophageal veins without hemorrhage or ascites. Of 12 patients with ascites, 3 died immediately after surgery, and 1 died 6 months after surgery; 8 patients showed improvement. Of 10 patients with hemorrhage (8 had cirrhosis and 2 had subhepatic block of portal circulation), 1 patient died 3 months after ligation, and 2 had recurrences of the hemorrhage (2 yr and 4 yr after surgery, resp.). Both patients with varicose esophageal veins had intrahepatic block of portal circulation; ligation of the splenic artery reduced portal pressure. They were alive and in satisfactory condition 1 and 3 yr, resp., after surgery.

6535 LONG-TERM RESULTS OF SPLENIC ARTERY LIGATION FOR PORTAL HYPERTENSION. (Rus.)

Zubarev, P. N. (S. M. Kirov Military-Medical Acad., Leningrad, USSR). *Vestn. Khir.* (6):47-50; 1977.

The efficacy of splenic artery ligation for the treatment of portal hypertension was evaluated in 17 patients with cirrhosis and in 18 patients with extrahepatic portal hypertension without cirrhosis. Indications for ligation were hemorrhage (16 patients), hypersplenism (10), and ascites (3); six patients had several indications for surgery. Within 8 days to 2 months of ligation, five patients with cirrhosis died (3 of hepatic insufficiency, and 2 of peritonitis); six patients with cirrhosis died within 1-4 yr of surgery (4 of hemorrhage), and six patients were alive for 11, 10, 8, 4, 3, and 2 yr, resp. Of 18 patients with extrahepatic portal hypertension, 2 died of recurrent hemorrhage within 2-5 yr, and 1 died 2 yr 3 months later of diffuse peritonitis; only 3 patients were hemorrhage-free for 1-2 yr. Splenic artery ligation resulted in a decrease of splenic size in 18 surviving patients and in a decrease of portal tension.

6536 EFFECT OF D-PENICILLAMINE ON COPPER RETENTION IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS. (Eng.)

Deering, T. B.; Dickson, E. R.; Fleming, C. R.; Geall, M. G.; McCall, J. T.; Baggenstoss, A. H. (Mayo Clinic, 200 First St. S.W., Rochester, MN 55901). *Gastroenterology* 72(6):1208-1212; 1977.

As part of a double blind, randomized trial evaluating D-penicillamine in primary biliary cirrhosis, urinary copper excretion and hepatic copper concentration were monitored during the 1st year of therapy in 46 patients with cirrhosis. The retention of copper in primary biliary cirrhosis was confirmed by abnormally high levels of copper in almost all patients before treatment. The hepatic copper was elevated (>35 μg/g dry weight) in 43 of 45 patients, the urinary copper was elevated (>45 μg/24 hr) in 42 of 46, and the ceruloplasmin was elevated (>43 mg/dl) in all 46. Urinary copper excretion correlated with the hepatic copper concentration ($r = 0.68$, $p \leq 0.001$). No significant correlation occurred between hepatic copper and ceruloplasmin. Hepatic copper concentrations greater than 400 μg/g of dry weight were found almost exclusively in patients with advanced histological disease ($p \leq 0.01$). Therapy with D-penicillamine (250 mg/day, p.o., increased stepwise to 1 g/day, p.o., over a 4-week period) and a low copper diet sustained increased urinary copper excretion for 1 yr in almost all patients ($p \leq 0.001$). Among patients taking placebo, the median hepatic copper concentration increased 13 μg/g of dry weight after 1 yr. In contrast, among the patients taking D-penicillamine, the median hepatic copper concentration decreased 99 μg/g of dry weight ($p \leq 0.02$). Continued observation of this therapeutic trial may help to clarify the relationship of copper retention and liver injury in primary biliary cirrhosis.

6537 CIRRHOTIC PLEURAL EFFUSION IN THE ABSENCE OF ASCITES. (Eng.)

Singer, J. A.; Kaplan, M. M.; Katz, R. L. (New England Medical Center Hosp., 171 Harrison Ave., Boston, MA 02111). *Gastroenterology* 73(3):575-577; 1977.

The case of a patient with cirrhotic pleural effusion in the absence of ascites and other stigmata of chronic liver disease is presented. The patient, a 61-yr-old woman, presented with increasing dyspnea and a 1-month history of ankle edema. A chest x-ray demonstrated a large right pleural effusion with a shift of the mediastinum to the left. The SGOT level was 71 IU, SGPT 36 IU, alkaline phosphatase 4.0 Bodansky U, and total bilirubin 1.6 mg/100 ml. Pleural fluid was drained at a rate of 3.0 l/day; this fluid became transiently bloody. The patient became lethargic, and asterixis was noted; her mental status improved with treatment for hepatic encephalopathy. A liver scan revealed hepatosplenomegaly, and a liver biopsy revealed postnecrotic cirrhosis. An abdominal echo revealed no ascites. The pleural effusion cleared over several weeks with salt restriction and diuretic therapy; however, a recurrent effusion 3-4 months later failed to respond to medical therapy. Ascites were again absent. She developed symptomatic hyponatremia, requiring the administration of hypertonic saline; this led to the appearance of ascites for the first time. At autopsy there was approximately 200 ml of ascitic fluid that readily flowed through a 1-mm hole in the tendinous portion of the right hemidiaphragm when the body was tilted. The lack of acute or chronic inflammation and the absence of hemosiderin in the connective tissue adjacent to the defect suggested that local trauma did not play a role in its production.

6538 PERCUTANEOUS TRANSHEPATIC CATHETERIZATION OF THE PORTAL VEIN FOR THE STUDY OF PORTAL HEMODYNAMICS AND SHUNTS: A PRELIMINARY REPORT. (Eng.)

Okuda, K.; Suzuki, K.; Musha, H.; Arimizu, N. (Chiba Univ. Hosp., Chiba, Japan 280). *Gastroenterology* 73(2):279-284; 1977.

A technique for catheterizing the portal vein transhepatically, based on the authors' method for percutaneous transhepatic cholangiography, is described, and its use in 21 patients with hepatic cirrhosis, 4 with idiopathic portal hypertension, 2 with hepatic steatosis, 2 with chronic hepatitis, and 1 with drug-induced cholestatic hepatitis is reported. Using this technique, quantitation of the intrahepatic shunt and extrahepatic shunt from the splenoportal axis is possible. It involves injection of ^{99m}Tc-macroaggregated albumin into the splenic vein at the splenic hilum and injection of ^{131}I-macroaggregated albumin into the portal trunk, followed by differential counting over predetermined areas of the liver and lungs. Catheterization was successful in 20 of the 30 patients. The intrahepatic shunt indices varied from 1.0 to 78.4% and the extrahepatic shunt indices ranged from 0 to 49.9%. These values appeared to correlate closely with the size of collaterals opacified by portography.

6539 ISOLATED CIRRHOSIS OF LEFT LIVER LOBE. (Rus.) Kuzin, A. I. (Rostov Medical Inst., USSR). *Khirurgiia* (7):133-135; 1977.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

6540 ENDOTOXIN AND BACTERIA IN PORTAL BLOOD. (Eng.) Jacob, A. I.; Goldberg, P. K.; Bloom, N.; Degenshein, G. A.; Kozinn, P. J. (Maimonides Medical Center, 4802 10th Ave., Brooklyn, NY 11219). *Gastroenterology* 72(6):1268-1270; 1977.

To determine whether endotoxin is normally found in the portal system, intraoperative samples of portal and peripheral blood were drawn from 34 consecutive elective abdominal surgery patients. The limulus lysate test was used to detect endotoxin. Twenty-four patients had samples of portal and systemic blood taken just before the conclusion of surgery; 10 patients had samples taken at the beginning of surgery, before any manipulation of the bowel. Ninety-seven percent of all patients had a positive limulus test in portal blood. Twelve of these patients were tested for portal bacteremia, and only one showed growth. Four patients also had systemic endotoxemia; three of these had liver disease, and one had a gram-negative sepsis. This study demonstrates that endotoxin is a normal constituent of portal venous blood in man and does not represent a pathological process. It is suggested that the Kupffer cells of the liver normally protect the systemic circulation from endotoxin, and that endotoxin is present in systemic blood only when liver function is impaired or gram-negative bacteremia is present.

6541 STUDIES ON THE BIOSYNTHESIS OF ALBUMIN AND PROTEINS IN HUMAN LIVER TISSUE. (Eng.) Lundholm, K.; Schersten, T.; Lindstedt, G.; Lundberg, P. A. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Eur. J. Clin. Invest.* 7(4): 275-282; 1977.

Human hepatic albumin and protein biosyntheses were studied by determining the incorporation rate of leucine into albumin and the incorporation rate of leucine into hepatic proteins in liver slices. Leucine was linearly incorporated into hepatic tissue albumin, into albumin released into the incubation medium, and into hepatic proteins during 4 hr incubation. Amino acids stimulated the albumin and hepatic protein synthesis *in vitro* and *in vivo*. The incorporation rate of leucine into hepatic albumin and tissue proteins was correlated with hepatic RNA concentration. In 21 experiments, the mean incorporation rate of leucine into hepatic tissue immunoreactive albumin was 5.1 ± 0.6 μmol/leucine/hr/g albumin and 0.87 ± 0.17 μmol leucine/hr/g albumin into albumin released to the incubation medium. By crossed immunoelectrophoresis, the hepatic immunoreactive albumin could be partly resolved into two components, one of which migrated at the same rate and the other at a lower rate than serum albumin. Treatment of the slowly migrating component with a low concentration of trypsin (0.2 μg/100 μg of fraction) changed its mobility to that of serum albumin. Gel filtration through Sephadex G-100 of the slowly migrating fraction showed that it had a molecular size similar to that of serum albumin. The results support the hypothesis that human hepatic albumin biosynthesis involves a polypeptide precursor similar to that described for the rat liver.

6542 PHARMACOLOGY OF CHENODEOXYCHOLIC ACID. II. ABSORPTION AND METABOLISM. (Eng.) van Berge-Henegouwen, G. P.; Hofmann, A. F. (St. Radboud Hosp., Nijmegen, Netherlands). *Gastroenterology* 73(2):300-309; 1977.

The absorption and metabolism of chenodeoxycholic (chenic acid) were studied in healthy volunteers and gallstone patients on maintenance therapy with chenic acid for gallstone dissolution. Preliminary studies in two healthy subjects showed that chenic acid was completely absorbed in doses up to 400 mg when infused as a micellar solution into the jejunum. The increase in levels of unconjugated chenic acid in peripheral blood was directly proportional to dose, i.e., that a constant fraction of the administered dose appeared in peripheral blood, indicating that hepatic fractional clearance was constant in doses up to 400 mg. A preparation of ^{3}H-chenic acid (250 mg, p.o.) was completely absorbed. To test the bioavailability of the eight commercial preparations, 400 mg of a given preparation was mixed with 40 mg of ^{3}H-chenic acid. Radioactivity and unconjugated chenic acid, determined by gas-liquid chromatography, were measured in peripheral blood, and the ratio of mass to radioactivity was used to calculate absolute bioavailability. All preparations were completely absorbed, with the exception of one sample, which consisted of large crystals; after milling, this preparation was also completely absorbed. First-pass clearance was determined by comparing the integrals of the plasma concentration time curve after i.v. administered ^{14}C-chenic acid with those after simultaneous p.o. ingestion of ^{3}H-chenic acid; it averaged 62%. Chenic acid was completely absorbed in gallstone patients on maintenance chenic acid therapy, irrespective of whether the agent was ingested during fasting, with meals, or 1 hr after a meal. After ingestion of ^{3}H-chenic acid, all radioactivity in peripheral blood had the chromatographic behavior of unconjugated chenic acid, suggesting that no biotransformation occurred during intestinal absorption. Chenic acid, administered i.v., was promptly excreted in bile as its glycine and taurine conjugates. These studies indicate that chenic acid, if sufficiently small in particle size, is rapidly and completely absorbed, efficiently extracted by the liver, and excreted in bile as chenodeoxycholyl conjugates.

6543 INORGANIC PHOSPHORUS IN HUMAN BILE. (Eng.)

Sutor, D. J.; Wilkie, L. I. (Dept. Chemistry, Univ. Coll., Gower St., London WC1E 6BT, England). *Clin. Chim. Acta* 77(1):31-36; 1977.

Inorganic phosphorus (Pi) concentration was measured in fresh bile from patients undergoing cholecystectomy, usually because of cholelithiasis. Common duct bile Pi was significantly greater ($p<0.01$) for patients with cholesterol on the stone surface (0.45 ± 0.03 mM; range, 0.17-0.90 mM) than for patients with some calcium carbonate on the stone surface (0.20 ± 0.03 mM; range, 0.09-0.28 mM). For patients with functioning gallbladders, Pi in common duct bile was always less than that in gallbladder bile. The ratio of Pi in gallbladder bile/Pi in common duct bile was significantly greater ($p<0.02$) for patients with some calcium carbonate on the stone surface (3.87 ± 0.20) than for those with only cholesterol on the stone surface (2.28 ± 0.42). For six cholesterol-stone formers, there was a significant correlation ($p<0.03$) between Pi in the common duct bile and Pi in the gallbladder bile. In bile from functioning gallbladders, Pi was linearly related to pH for cholesterol-stone formers ($p<0.001$), but was not related to pH for calcium carbonate-stone formers. The results indicate that bile from calcium carbonate-stone formers is more dilute with respect to Pi, and probably also than cholesterol-stone formers.

6544 ROUTINE PREOPERATIVE UPPER GASTROINTESTINAL SERIES (UGIS) IN PATIENTS WITH BILIARY TRACT DISEASE: A PLEA FOR MORE SELECTIVITY.

(Eng.) Max, M. H.; Polk, H. C., Jr. (Univ. Louisville Sch. Medicine, Louisville, KY 40201). *Surgery* 82(3):334-336; 1977.

The clinical value of upper gastrointestinal roentgenograms was assessed in 250 patients who had consecutive cholecystectomies performed in one hospital. One hundred and five of these patients did not have upper gastrointestinal series (UGIS) prior to operation, and no gastroduodenal disease was discovered at operation. Thirty-nine positive x-ray examinations were obtained among the 145 patients who had preoperative UGIS. In only three of these patients was a gastric procedure added at operation; no unexpected cancers were found. In the other 36, "positive" findings consisted of (1) small hiatal hernias, (2) diverticula of the esophagus, stomach, or duodenum not clinically significant, or (3) postgastrectomy anatomic abnormalities. This review suggests that routine preoperative UGIS may not be warranted in such patients and urges greater selectivity of patients having this procedure.

6545 COMPLICATIONS AND ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY: A REVIEW OF THE LITERATURE AND PRESENTATION OF A DUODENAL PERFORATION.

(Eng.) Ihre, T.; Hellers, G. (Serafimer Hosp., Stockholm, Sweden). *Acta. Chir. Scand.* 143 (3):167-171; 1977.

The case of a patient in whom duodenal perforation occurred during endoscopic retrograde cholangiopancreatography (ERCP) is presented, and the literature concerning complications in association with ERCP is reviewed. The patient, a 68-yr-old woman, underwent ERCP because of recurrent cholangitis. At the first attempt to perform ERCP, one of the maneuvering wires broke, and gas was insufflated through the instrument into the biliary tree. ERCP was again attempted several days later, at which time it was again very difficult to pass the instrument into the descending duodenum. The perforation occurred at this time. The cannulation of the papilla was performed in the usual manner. At laparotomy 3 hr later, the perforation was found to penetrate into the lesser sac at the top of the right side of the duodenum about 4 cm from the pylorus. The perforation was closed, and a choledochotomy was performed. The rate of complications in ERCP is estimated to be 2.6%. Fifty percent of these are due to pancreatitis, and 30% are due to cholangitis. The mortality rate is 0.1%, and all reported deaths have occurred in patients with pancreatitis or cholangitis. The frequency of perforation occurring in ERCP is estimated to be about 0.05%.

6546 INITIAL EXPERIENCE OF PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY USING A FINE GAUGE NEEDLE. (Eng.) Lavelle, M. I.; Owen, J. P.; McNulty, S.; Hamlyn, A. N. (Royal Victoria Infirmary, Newcastle upon Tyne, England). *Clin. Radiol.* 28(4):453-456; 1977.

Experience with percutaneous transhepatic cholangiography using a fine gauge (Chiba) needle on 41 occasions in 40 patients with jaundice or abnormal liver function is reported. The ages of the patients ranged from 3 months to 80 yr, and the youngest successful cannulation was carried out on a 15-month-old child. There were 32 cases of extrahepatic biliary obstruction, the site being shown in 28 (87.5%) and the nature correctly predicted in 22 (69%). One of two patients in the post obstructive phase and one of two with intrahepatic cholestasis were cannulated and showed bile ducts of normal caliber. Three of four patients with hepatocellular disease were successfully examined, and obstruction was excluded by showing normal bile ducts. Delayed films taken up to 2 hr later were found valuable, particularly in cases of obstructive jaundice. The technique is easier and less expensive to perform than endoscopic retrograde cholangiography. No major complications occurred, suggesting that the modified technique is now a safe procedure for investigating jaundice or disordered liver function in both adults and children.

6547 INVESTIGATION OF THE NON-JAUNDICED PATIENT BY PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. (Eng.) Frankel, M.; Gordon, R. L. (Hadassah Univ. Hosp., Jerusalem, Israel). *Clin. Radiol.* 28 (2):129-135; 1977.

Percutaneous transhepatic cholangiography was successfully used to obtain diagnostic examinations n 15 consecutive non-jaundiced patients. After remedication with meperidine, promethazine, and tropine, a Longdwell 6-inch, 18-gauge needle enheathed with a teflon cannula was passed rapidly nto the liver during apnea. The point of entry as in the eighth or ninth intercostal space in he right midaxillary line. The needle was reoved, leaving the teflon cannula in place, and hallow breathing was resumed. The cannula was lowly withdrawn until bile was obtained freely. he above lateral approach is preferred to other pproaches because there is less danger of puncturng the gallbladder or common bile duct. Bile as aspirated before the injection of 30-100 ml rografin 60 under fluoroscopy, and radiographs ere taken. As much bile and contrast medium as ossible were aspirated before the cannula was emoved. In 10 patients, the method was successul in establishing the presence or absence of tones or other operable lesions after previous liary surgery. The method was also successful in establishing the diagnosis in three patients with highly suggestive biliary histories who had not undergone previous biliary surgery and in providing detailed anatomical information in one patient with a choledochal cyst and in another patient with a common duct stricture after cholecystectomy. Complications associated with this diagnostic procedure were minimal.

6548 GRAY-SCALE ULTRASONOGRAPHY AND THIN-NEEDLE CHOLANGIOGRAPHY: EVALUATION IN THE JAUNDICED PATIENT. (Eng.) Goldstein, L. I.; Sample, W. F.; Kadell, B. M.; Weiner, M. (Univ. California Los Angeles Center for the Health Sciences, Los Angeles, CA 90024). *JAMA* 238(10):1041-1044; 1977.

Gray-scale ultrasonography (GSU) and thin-needle cholangiography (TNC) were carried out in 35 consecutive patients with unexplained jaundice to assess the ability of GSU to distinguish dilated and nondilated bile ducts in such patients. The status of the biliary tree was correctly assessed by GSU in 33 of 35 cases; in 2 patients, technical difficulty prevented definitive assessment. Neither false-positive nor false-negative results were encountered. There were no discrepancies between the results of GSU and TNC. It is concluded that GSU provides a safe, highly reliable method of assessing the jaundiced patient and should be the preferred initial procedure in the diagnostic evaluation of patients with jaundice when the major differential diagnosis lies between the medical and surgical types. If GSU does not demonstrate a dilated biliary system, TNC is unnecessary, and other diagnostic studies should be undertaken.

6549 VISUALIZATION OF THE COMMON BILE DUCT DURING CAERULEIN CHOLECYSTOGRAPHY. (Eng.) Fujita, R.; Matsumoto, K.; Ikeda, T. (Tokyo Metropolitan Cancer Detection Center, Tokyo, Japan). *Acta Gastroenterol. Belg.* 40(3/4):167-174; 1977.

Cerulein (0.2 g/kg, i.m.) was used as a cholecystokinetic agent during oral cholecystography, and the frequency of common bile duct visualization obtained with cerulein was compared with that obtained with yolk product. Thirty-nine normal subjects, 20 patients with cholelithiasis, and 8 patients with a nonvisualized gallbladder received yolk product. Forty-three normal subjects, 16 patients with cholelithiasis, 2 patients with common duct dilation, and 6 patients with a nonvisualized gallbladder received cerulein. X-rays were taken before and 5, 10, 15, and 30 min after the injection of cerulein or yolk product. If patients in whom the gallbladder was not visualized were excluded, visualization of the common bile duct was obtained in 64.0% of the patients who received cerulein and in only 3.4% of those who received yolk. Visualization of the common bile duct was achieved 5-15 min after the injection. The frequency of common bile duct visualization was lower in the patients with cholelithiasis (56%) than in the normal subjects (67%). The common duct was not visualized in 22 cases. Among these, six patients showed poor gallbladder contraction and five showed poor gallbladder visualization. The results suggest that a high rate of common bile duct visualization can be obtained using cerulein.

6550 VISUALIZATION OF THE GALLBLADDER WALL AT EXCRETORY UROGRAPHY: IMPLICATION FOR INFUSION TOMOGRAPHY OF THE GALLBLADDER.

(Eng.) Morin, M. E.; Baker, D. A.; Marsan, R. E. (Veterans Admin. Lakeside Hosp., 33 E. Huron St., Chicago, IL 60611). *Radiology* 125(1):35-38; 1977.

A prospective study was undertaken in 2,867 patients who received excretory urography at one institution during a 2-yr period to determine whether the normal gallbladder wall is demonstrable through examination of conventional excretory urogram images. Of these patients, 63 had clear visualization of a curvilinear opacified density surrounding a right upper quadrant (RUQ) lucency thought to represent the gallbladder wall and lumen, resp. This visualization was apparent in at least two images in all patients. None of the 63 patients had epigastric, right flank, or RUQ pain at the time of the urogram, or at any time during hospitalization. Of 23 patients returned for p.o. cholecystography, the gallbladder was well-visualized in 21, and gallstones were present in only 2. Confirmation of the curvilinear RUQ density as the gallbladder wall was provided in 21 patients by p.o. cholecystography, and by an additional image with patient positioning and beam-centering identical to the excretory urogram. The data indicate that the normal gallbladder wall can be demonstrated during i.v. infusion of diatrizoate. This suggests that visualization of the normal gallbladder wall occurs frequently enough to severely limit the usefulness of infusion tomography of the gallbladder in the diagnosis of cholecystopathies.

6551 ENDOSCOPIC LITHOTRIPSY IN THE COMMON BILE DUCT.

(Eng.) Koch, H.; Stolte, M.; Walz, V. (Medizinische Universitats Klinik, 8530 Erlangen, W. Germany). *Endoscopy* 9(2):95-98; 1977.

A new method of lithotripsy and its use in human bile duct stones is described. The method involves the use of a lithotripsy probe, to which a Dormia basket is attached. The common duct stones found in 20 cadavers were crushed. Electrohydraulic lithotripsy was then carried out in three patients in whom stones in the common bile duct were so large that they could not be extracted even after extensive papillotomy. In all patients, the common duct was first filled with contrast medium to facilitate the localization of the stones. After the probe was introduced into the common duct, the Dormia basket was advanced; the stone was caught in the basket and drawn up against the tip of the probe. A hypertonic liquid (30% glucose and physiological saline) was instilled via the probe channel, and the spark discharges were then triggered. The calculi were fragmented in all three patients, but subsequent stone extraction was possible in only one case. No complications occurred.

6552 ELECTROENTEROGRAPHY AFTER CHOLECYSTECTOMY: THE ROLE OF HIGH EPIDURAL ANALGESIA.

(Eng.) Gelman, S.; Feigenberg, Z.; Dintzman, M.; Levy, E. (Beilinson Medical Center, Petah Tikva, Israel). *Arch. Surg.* 112(5):580-583; 1977.
1977.

To investigate the effect of high epidural analgesia on stomach and intestinal motility following upper abdominal surgery, the electrical activity of the stomach and intestine was monitored during the postoperative period in 30 patients who underwent cholecystectomy. All patients received standard general anesthesia with artificial ventilation during the operation; some received high epidural analgesia during surgery and postoperatively, and others, fentanyl analgesia during surgery and nicomorphine afterwards. Electroenterography (EEnG) showed that electrical activity decreased following surgery and returned to base line on the third or fourth day after surgery. A marked increase in amplitude and frequency of EEnG oscillations was recorded in 80% of the patients who received bupivacaine injections into the epidural space. A decrease was almost always recorded after nicomorphine injections. During the postoperative period, eating caused a considerable increase in the amplitude and frequency of the electrical activity of the stomach and intestine in patients treated by epidural analgesia, whereas no observable change was recorded in patients treated by nicomorphine injections. It appears that high epidural analgesia may be useful in the treatment of postoperative adynamic ileus.

6553 CAUSES OF POSTCHOLECYSTECTOMY SYNDROME AND ITS PREVENTION.

(Rus.) Kravchuk, A. N.; Karaman, N. V.; Zimovsky, V. L. (Clinic Faculty and Hosp. Surgery, Medical Inst., Odessa, USSR). *Khirurgiia (Mosk.)* (3):39-43; 1977.

Postcholecystectomy syndrome in a group of 230 patients is reviewed. The patients underwent extensive clinical examination, infusion cholangiography, transparietal cholangiography, and functional testing of the liver, spleen, intestine, and kidneys. The patients could be divided into two groups. Group 1 included 103 patients in whom the pain was found to be due to previous surgery. The patients in group 1 could be further divided into two subgroups. Group B consisted of 47 patients with calculus in the common bile duct and strictures of the papilla of Vater, which were overlooked during surgery; in group A, 49 patients had commissures and stenosis of the common bile duct and duodenum, bile fistulas, and subhepatic abscesses. Only seven group A patients with chronic cholecystitis subjected to surgery without sufficient indications had "true" postcholecystectomy syndrome. Group 2 included 127 patients in whom pains were not associated with surgery and were due to chronic pancreatitis (45); concomitant lesions of the liver (32); gastritis, pericholedochal lymphadenitis, recurrent cholangitis, or ulcer disease (11); duodenostasis (7); stenocardia (2); and urolithic disease (11). Prophylaxis of postcholecystectomy syndrome should consist of surgical treatment of chronic cholecystitis.

6554 INFLUENCE OF BILIARY INFECTION ON THE POSTOPERATIVE COURSE AFTER BILIARY TRACT SURGERY.

(Eng.) Wolloch, Y.; Feigenberg, Z.; Zer, M.; Dintsman, M. (Beilinson Medical Center, Petah Tikvah, Israel). *Am. J. Gastroenterol.* 67(5):456-462; 1977.

A prospective clinicobacteriological study was
carried out in 167 patients undergoing biliary sur-
gery to assess the possible influence of endoge-
nous preoperative biliary infections on postoper-
ative morbidity. Bile cultures were positive in
33% (55 patients); in those undergoing cholecystec-
tomy alone, this finding was present in 23%, while
in those in whom a choledochotomy was also performed,
cultures were positive in 65%. The incidence of
wound infection was twice as high in those under-
going choledochotomy as in those undergoing chol-
ecystectomy alone (37.8% versus 18.5%). There was
no appreciable difference in the rate of wound
infection when a routine appendectomy was performed
during biliary tract surgery. Among the 38 patients
with wound infection, bile cultures were positive in
.6. In 13 cases, the offending organism in the
wound was identical with that recovered from the
bile culture. This result suggests an endogenous
ource for the wound infection. Wound infection
as most likely to be encountered in patients with
athogenic organisms in the bile, in the aged, and
n those whose resistance to infection had been
owered by concomitant disease.

555 GLUTATHIONE LEVEL IN THE VENOUS BLOOD IN PATIENTS WHO UNDERWENT OPERATION ON THE ILE DUCTS.

(Rus.) Sobchishin, Iu. V.; Valigura,
a. S.; Gerasimenko, A. A.; Vanat, I. M. (Terebov-
ianskaia Central Regional Hosp., Terebovlianskaia,
ernopol Oblast, USSR). *Vrach. Delo* (11):72-74;
976.

he functional state of the liver and tissue res-
iration were studied in 106 patients undergoing
urgery for various lesions of the liver and bil-
ary ducts. Thirty patients had acute cholecys-
itis, 28 had chronic calculous cholecystitis with-
ut jaundice, 34 had jaundice, and 14 had obstruc-
ive jaundice due to cancer. The level of blood
lutathione and activities of serum alanine and
spartate aminotransferase (AlAT and AsAT) were
ssessed preoperatively and on days 2-4 and 10-12
fter surgery. Surgery included cholecystectomy,
-pass anastomoses, hepaticotomy, and choledocho-
omy. Preoperatively, a majority of the patients
d tissue hypoxia; severity of hypoxia was asso-
ated with severity and duration of the inflam-
tory process. A postoperative decrease of the
utathione level was indicative of a decrease in
ssue hypoxia; the most pronounced decrease in
poxia was observed in patients with acute chole-
stitis. The functional state of the liver in
e patients with acute and chronic cholecystitis
days 2-4 after surgery showed deterioration, while in the patients with cholestasis, the liver function was significantly improved.

6556 THE CLINICAL SIGNIFICANCE OF INCREASED PLASMA LEVELS OF LIVER-SYNTHESIZED COAGULATION FACTORS IN LIVER DISEASE.

(Eng.) Arnman, R.; Iwarson, S.; Olsson, R. (Sahlgren's Hosp., S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 12 (4):387-389; 1977.

Plasma coagulation factor II-VII-X levels were determined in 38 patients with common duct stones, 55 with hepatitis A, 34 with hepatitis B, 33 with bile duct obstruction due to pancreatic carcinoma, 8 with hepatocellular drug reaction, and 5 with cholestatic drug reaction. The first plasma factor II-VII-X value after admission to the hospital was higher than 90% in 29% of the common duct stone patients, in 9% of the patients with bile duct obstruction due to pancreatic carcinoma, and in 60% of the patients with cholestatic drug reaction. In contrast, the admission value was above 90% in only one of the 89 patients with acute hepatitis and in none of the patients with a hepatocellular drug reaction. Therefore, a high plasma factor II-VII-X activity in a patient with liver or biliary tract disease seems to be a reliable indicator of surgical disease. The high activity levels may be explained by an increased protein synthesis in the liver.

6557 ENZYMOLOGICAL INVESTIGATIONS IN DISEASES OF THE BILE DUCTS.

(Rus.) Avdei, L. V.; Rashchinskaia, N. T.; Vit'ko, I. M. (Second Dept. Surgery, Minsk Medical Inst., Minsk, USSR). *Vestn. Khir.* 117(12):35-40; 1976.

The efficacy of enzymologic evaluation for the differential diagnosis and prognosis of liver lesions was studied in 255 patients with various forms of cholecystitis. There were 21 patients with acute phlegmonous cholecystitis, 11 with acute gangrenous cholecystitis, 150 with chronic cholecystitis, 38 with obstructive jaundice, and 35 with chronic cholecystopancreatitis. All patients underwent surgery. Preoperatively and on days 3, 7, 10, and 12 after surgery, the patients underwent assessment of activity of the following enzymes: aspartate amino transferase (AsAT), alanine amino transferase (AlAT), fructose-1,6-diphosphate aldolase (F-1,6-dA), alkaline phosphatase (AP), lactate dehydrogenase (LDH), glucose-6-phosphate dehydrogenase (G-6-PD), 6-phosphogluconic acid dehydrogenase (6-PGD), and transketolase (TK). Preoperatively, the patients with gangrenous cholecystitis and obstructive jaundice had increased activities of F-1,6-dA; surgery resulted in normalization of F-1,6-dA activity. Preoperatively, all patients had increased activity of AsAT and AlAT, which showed further elevation on day 3 after surgery. Activity of AP was elevated in the blood sera of obstructive jaundice patients and those with acute gangrenous cholecystitis. Maximum preoperative activity of LDH was detected in the patients with obstructive jaundice; the patients with cholecystopancreatitis and chronic cholecystitis had significant elevation of LDH activity. It is concluded that observed changes in enzymes activity are indicative of involvement of the liver parenchyma into pathologic process and, thus, can not be used for differential diagnosis of bile duct lesions.

6558 CHOLEDOCHODUODENOSTOMY IN THE TREATMENT OF BENIGN BILIARY TRACT DISEASE. (Eng.)

Freund, H.; Charuzi, I.; Granit, G.; Berlatzky, Y.; Eyal, Z. (Hadassah Univ. Hosp., P.O. Box 499, Jerusalem, Israel). *Arch. Surg.* 112(9):1032-1034; 1977.

Experience with 27 patients who underwent choledochoduodenostomy (CCD) for benign obstructive lesions of the biliary tract (residual or recurrent common duct stones, 16; multiple stones, 16; hepatic duct stones, 5; roentgenographic evidence of papillary stenosis, 9; pancreatitis, 1; and a very dilated common bile duct, 25) is presented. Sixteen patients had undergone previous biliary tract surgery. Twenty-two of the patients were 70-90 yr old at the time of CCD, and the 11 patients in whom CCD was performed as a primary procedure averaged 73 yr old. There was no operative or hospital mortality, although complications occurred in 12 patients. Of 26 patients followed up for 6 months to 8 yr, 25 were free of abdominal complaints, recurrent acute cholangitis, or pancreatitis; only 1 patient developed cholangitis 6 yr after CCD. An upper gastrointestinal tract study revealed a stenosed anastomosis, with contrast material quickly filling the biliary system but emptying slowly. Stones were demonstrated in the segment between the anastomosis and the papilla. The patient responded to antibiotic therapy. These favorable results indicate that CCD is a safe, simple, and effective procedure in the management of benign biliary tract disease, particularly in high-risk patients.

6559 AGENESIS OF THE GALLBLADDER--AN INHERITED DEFECT? (Eng.)

Sterchi, J. M.; Baine, R. W.; Myers, R. T. (Bowman Gray Sch. Medicine, Winston-Salem, NC 27103). *South. Med. J.* 70(4):498-499; 1977.

The case of a patient with agenesis of the gallbladder is presented. The patient, a 36-yr-old woman, presented with vague epigastric pain and occasional episodes of nausea and vomiting not related to the ingestion of a fatty meal. At exploratory celiotomy, no intra-abdominal abnormalities except the absence of the gallbladder were found. The usual gallbladder fossa did not exist and there were no adhesions on the undersurface of the right lobe. There was no cystic duct. An intraoperative needle cholangiogram revealed a common duct 5-6 mm in diameter, but no evidence of an intrahepatic gallbladder. The patient's father and one of her four children (a 12-yr-old girl) were also discovered to have gallbladder agenesis. This congenital anomaly should be suspected when oral cholecystography shows a nonvisualizing gallbladder in relatives of any patient with proven agenesis of the gallbladder.

6560 PRIMARY GALLBLADDER CARCINOMA. (Ger.)

Voigtsberger, P.; Neupert, V., Pathe, H. (Chirurg. Klinik und Poliklinik, Nordhauser Strasse 74, 50 Erfurt, E. Germany). *Z. Gesamte Inn. Med.* 31(20):856-859; 1976.

Survival rate, clinical findings, and therapeutic management, including test laparotomy (51 cases), cholecystectomy (8), cholecystostomy (1), and biliodigestive anastomosis (4), are discussed for 77 patients with gallbladder carcinoma. The most frequent symptoms were pain (unspecified), vomiting, anorexia, and weight loss. Also observed was an increase in th erythrocyte sedimentation rate, hepatomegalia, jaundice, and anemia (unspecified). Radiological diagnosis, in the form of a cholecystogram, was frequently negative. Surgical intervention was performed in 64 cases, 57 of which were histologically documented as adenocarcinomas. The average survival period after laparotomy was 53 days. Thirty-four patients survived more than 1 yr. Cholecystolithiasis was documented in 54 cases by surgery or autopsy. There was false evidence of lithiasis in three cases.

6561 BILIARY CARCINOMA ASSOCIATED WITH BILIARY CYSTS. (Eng.)

Flanigan, D. P. (St. Joseph Mercy Hosp., P.O. Box 995, Ann Arbor, MI 48106). *Cancer* 40(2):880-883; 1977.

The case of a patient with biliary carcinoma associated with biliary cyst is presented, and 23 similar cases are reviewed. The patient underwent cholecystectomy at 26 yr of age and 3 yr later, presented with obstructive jaundice. A 6-cm fusiform biliary cyst involving the common bile duct and distal common hepatic duct was discovered. Three stones were found within the cyst and removed. Biopsy of the cyst wall revealed chronic inflammation, but no neoplasm. A choledochocystduodenostomy was performed. Five years later, a common bile duct stricture proximal to the cyst was found, but it was not biopsied. A Roux-en-y choledochojejunostomy was performed proximal to the stricture. Recurrent symptoms of obstructive jaundice led to the discovery of a well-differentiated adenocarcinoma in the area of a 2-cm-long stricture of the common bile duct proximal to the choledochojejunostomy. Of all 24 reported cases in which carcinoma developed, stones were present in the cyst in 6. The most common cell type was adenocarcinoma (70%), and the most common tumor site was in the posterior cyst wall (57%). Twelve patients developed carcinoma in a mean period of 4 yr following an internal drainage procedure for biliary cystic disease. Of the cases of biliary cysts associated with cystlithiasis, one-third had associated biliary carcinoma. Excisional therapy should be carried out where possible in all patients with biliary cystic disease, particularly, those with associated cystlithiasis.

6562 PRIMARY SCLEROSING CHOLANGITIS. (Eng.) Ford, J. R. (2534 Imperial Ave., San Diego, CA 92102). *Int. Surg.* 62(6/7):332-333; 1977.

The case of a 44-yr-old man with sclerosing cholangitis is presented. The patient presented with jaundice and elevated serum bilirubin (12 mg/100 ml, direct), SGPT (151), LDH (520), and alkaline phosphatase (10.8). Surgery revealed a very hard mass that involved the right hepatic duct, the left hepatic duct, common hepatic duct, hepatic artery, portal vein, and cystic artery. The cystic duct and common hepatic duct were like hard cords with no cannulation possible. The gallbladder was atrophic and contained no stones. The blood supply to the area was increased, and many of the vessels going to the portal vein were thrombosed, as well as a portion of the common duct. At intraoperative cholangiography, there was no filling of the common duct or the bifurcation of the common hepatic duct. As much of the diseased liver and biliary tree as possible was resected. A T-tube could not be used because of extensive involvement of the duct; individual cannulizations of the hepatic ducts proved very successful. The patient developed two further episodes of cholangitis after this operation and responded to treatment with antibiotics and steroids. He is well 9 yr after surgery.

563 EFFICACY OF THERMOGRAPHY IN THE DIAGNOSIS OF CHRONIC CHOLECYSTITIS. (Rus.) Zhuk,
. A. (Ukrainian Inst. Advanced Training for Physi-
ians, Kharkov, USSR). *Vrach. Delo* (6):94-98; 1977.

he diagnostic value of thermography was studied in
1 patients with clinically confirmed relapse of
hronic cholecystitis; the duration of cholecystitis
anged from 2 yr to 14 yr. Temperature asymmetry
"hot" spot in the right hypochondrium) was detected
n 42 patients; the size and the intensity of the
pot were associated with the intensity of the in-
lammatory process. Negative thermographic findings
n nine patients may have been due to an excessive
at layer.

64 CHOLELITHIASIS IN SUBJECTS WITH HYPER-CALCAEMIA AND PRIMARY HYPERPARATHYROIDISM
TECTED IN A HEALTH SCREENING. (Eng.) Christens-
n, T.; Einarsson, K. (Dept. Medicine, Karolinska
st., Serafimerlasarettet, Stockholm, Sweden).
t 18(7):543-546; 1977.

e frequency of gallstone disease was studied in
subjects (69 women and 13 men; mean ages
.0 and 52.3 yr, resp.) with verified hyper-
lcemia (VHC) detected in a health screening in
e Stockholm area. Peroral cholecystography was
rried out in all noncholecystectomized subjects.
uses of hypercalcemia other than primary hyper-
rathyroidism (PHPT) had been excluded as far as possible. Sixty-two patients had been operated upon, and all but two men were found to have parathyroid adenomas. The patients were compared with a series of 82 normocalcemic age- and sex-matched subjects selected from the health screening register. The frequencies of gallstone disease in VHC and controls were 12% and 13%, resp., and the frequencies of gallstone disease in PHPT and controls were 12% and 14%, resp. The results are at variance with those of other investigators who have reported that PHPT is associated with an abnormally high frequency of gallstone disease.

6565 SERUM BILE ACIDS IN CHOLESTASIS OF PREGNANCY. (Eng.) Laatikainen, T.; Ikonen, E. (Univ. Central Hosp., Haartmaninkatu 2, SF-00290 Helsinki 29, Finland). *Obstet. Gynecol.* 50(3):313-318; 1977.

Determinations of maternal serum bile acid levels were compared with the results of routine liver function tests in patients with cholestasis of pregnancy; in addition, the occurrence of signs of fetal distress in these pregnancies was related to the severity of cholestasis as assessed by maternal serum bile acid levels. Using routine liver function tests, cholestasis of pregnancy was diagnosed in 86 pregnant women with pruritus. Serum aminotransferase levels were elevated in all patients, SGOT in 99%, and SGPT in 100%. In these patients, serum concentrations of cholic, chenodeoxycholic, and deoxycholic acids were determined using gas chromatography and were compared with those in a group of 40 uncomplicated pregnancies. Of these bile acids, cholic acid levels were elevated in 92% of the patients. The frequency of elevation of serum alkaline phosphatase was 49%, and total and conjugated bilirubin were elevated in 22% and 61%, resp. It appears that in addition to serum aminotransferase levels, the serum cholic acid concentration is a sensitive indicator of cholestasis of pregnancy. The cholestasis series was divided into three subgroups of increasing severity of cholestasis as assessed by maternal serum cholic acid levels, and the occurrence of signs of fetal distress was compared among these subgroups. The only intrauterine fetal loss occurred in the severe cholestasis group. The incidence of meconium-stained amniotic fluid also increased significantly in this latter group, and 21 of the 24 patients with other signs of fetal distress were in the groups of moderate and severe cholestasis.

6566 LIPOPROTEIN-X AND OTHER CLINICAL CHEMICAL PARAMETERS OF CHOLESTASIS. (Ger.) Mayr, K. (Allgemeines Krankenhaus, Grieskirchner Strasse 42, A-4600 Wels, Austria). *Wien. Med. Wochenschr.* 126(25/26/27):378-380; 1976.

The question of which clinical biochemical parameter is the most reliable indicator of the presence of cholestasis was investigated in 100 patients with intra- and extrahepatic cholestasis and 100 patients with hepatobiliary diseases other than cholestasis.

The serum transaminase and alkaline phosphatase activities, the serum bilirubin concentration, and the presence of lipoprotein X were the parameters studied. The presence of large amounts of lipoprotein X correlated with the presence of cholestasis. There was no other parameter, and no combination of parameters, that excluded or indicated the existence of cholestasis with greater reliability than did the presence of lipoprotein X. However, the presence of this substance did not permit any conclusion as to the etiology of cholestasis.

6567 DISSOLUTION OF CHOLESTEROL GALLSTONES BY URSODEOXYCHOLIC ACID. (Eng.) Nakagawa, S.; Makino, I.; Ishizaki, T.; Dohi, I. (Hokkaido Univ. Sch. Medicine, Sapporo, Japan). *Lancet* 2(8034):367-369; 1977.

A double blind clinical trial of p.o. ursodeoxycholic acid (UDCA) was carried out in 44 patients with radiolucent gallstones in gallbladders visible on cholecystography. The patients were randomly allotted to three treatment groups: 150 mg/day or 600 mg/day urosodeoxycholic acid or a placebo. At the end of 6 months' treatment, cholecystograms of all the patients were interpreted by radiologists who were not aware of the treatment. Dissolution of gallstones occurred in 8 (26%) of the 31 patients treated with ursodeoxycholic acid (6/16 treated with 150 mg, 2/15 treated with 600 mg), but not in the placebo group. Ursodeoxycholic acid had no hepatotoxicity, as assessed by standard liver function tests. These results indicate that ursodeoxycholic acid is effective in the dissolution of cholesterol gallstones.

6568 DISSOLUTION OF RETAINED COMMON DUCT STONES. (Eng.) Way, L. W.; Motson, R. W. (Univ. California Sch. Medicine, San Francisco, CA). *Adv. Surg.* 10:99-119; 1976.

Nonoperative methods to eliminate retained common duct stones via T-tube access after choledochotomy are reviewed, with particular emphasis on the use of cholate for the dissolution of cholesterol stones. The methods reviewed include dissolution, flushing, and pharmacologic relaxation of the sphincter of Oddi, usually as an adjunct to flushing. After initial attempts at the management of retained stones with mechanical extraction have failed, irrigation is recommended. The retained stone is usually discovered on cholangiograms performed a week or so after surgery. However, the T-tube tract should be allowed to mature and the patient to recover fully from choledochotomy before irrigation or other treatment options are instituted for stone removal. Solutions should not be instilled until any possibility that thay may leak from the choledochotomy into the paraductal planes has passed. Efforts at stone dissolution can only be expected to affect cholesterol stones, and therefore dissolution should probably not be tried in patients with retained radiopaque stones or in those whose gallbladder stones appear to be of the pigment variety. The treatment program for cholesterol stone dissolution involves the continuous infusion of a prefiltered sodium cholate solution (200 mM in 0.15 N NaCl buffered at pH 7.5) at a rate of 30 ml/hr for a period not exceeding 14 days. The patient must be given cholestyramine to prevent diarrhea.

6569 NONOPERATIVE EXTRACTION OF RETAINED COMMON DUCT STONES. (Eng.) Burhenne, H. J. (Children's Hosp., San Francisco, CA). *Adv. Surg.* 10:121-136; 1976.

Nonoperative techniques for the extraction of retained common duct stones are discussed. Nonoperative extraction is performed about 5 weeks after surgery to establish a better fibrous tract around the T-tube. The T-tube is extracted as the first step in the procedure. After the introduction of a steerable catheter into the sinus tract, cholangiograms are obtained to ascertain the exact number and location of retained stones. The steerable catheter is manipulated so that its tip is just beyond the location of the retained stone. A stone retrieval basket is introduced through the catheter and is opened distal to the stone. The steerable catheter is partially retracted, and the open basket is slowly withdrawn in an attempt to engage the stone. Several passes with the basket may be required before the stone is engaged. Large stones of 1 cm or more in diameter almost always require fragmentation. Only readily visible, major fragments are extracted on the first attempt; a straight catheter is then inserted, and the patient returns for a second session a few days later. For partially impacted distal common duct stones, special maneuvers to move the stone more proximally in the duct system may be required before stone extraction can be performed. One maneuver for mobilizing and engaging distal common duct stones employs the Fogarty balloon catheter. The Fogarty catheter is placed distal to the stone, and gentle traction is applied to cause upward displacement of the stone for basket engagement. Dilatation techniques with cylindrical balloons have been successfully employed in a few cases to permit subsequent stone extraction in patients with stones impacted in intrahepatic locations. Of 223 patients who underwent nonoperative stone extraction between 1971 and 1975, the removal of all stones was achieved in 95% of the cases. Failures occurred primarily in patients who had indwelling T-tubes of a number 12 F or less caliber. Two failures also involved cases where the T-tube had been placed through a midline incision.

6570 THE "JACK STONE" OR "MERCEDES BENZ" SIGN--A NEW THEORY TO EXPLAIN THE PRESENCE OF GAS WITHIN FISSURES IN GALLSTONES. (Eng.) Wright, F. W. (Churchill Hosp., Oxford, OX3 7LJ, England). *Clin. Radiol.* 28(4):469-473; 1977.

The occurrence of gas within clefts of fissures in gallstones is reviewed and speculation about its origin is presented. Three cases are discussed and radiographs of two of these patients published. The gallstones possessed crevices that contained gas and exhibited an appearance called the "Mercedes Benz" or "Jack Stone" sign. It is proposed that internal fissuring of the gallstones due to their crystalline structure produces a negative pressure that causes gases to come out of solution from the fluid in the stones. Then the outer layers of the stone seal off, preventing ingress of further fluid so that the negative pressure is maintained and the gas cannot redissolve. The finding of gas in x-rays of degenerate vertebral discs, degenerate symphysis pubis, and even manipulated joints is offered as supportive evidence for this model.

571 POSTOPERATIVE CHOLEDOCHOFIBERSCOPIC REMOVAL OF INTRAHEPATIC STONES. (Eng.)

Gocho, K.; Hiratsuka, H. (Hiratsuka Gastroenterolog-
ical Hosp., Tokyo, Japan). *Jpn. J. Surg.* 7(1):18-
27; 1977.

n endoscopic approach to the diagnosis and treat-
ent of intrahepatic stones is presented, based on
xperience with four cases in which complete removal
f intrahepatic stones was done by postoperative
holedochoscopy. The removal of stones was done
ith a two-channel choledochofiberscope containing
forceps outlet for the removal of stones in the
iliary tree and a saline outlet for irrigation so
hat the bile duct can be distended adequately for
irect observation. The choledochofiberscope also
ncorporated a light guide for illumination and an
bjective lens for visualization. The choledocho-
iberscope was inserted into the bile duct via the
holedochal fistula 3 weeks after surgery for the
emoval of stones. Stones not detected and removed
uring surgery were crushed or grasped with for-
eps under direct vision. In some cases, the
tricture in the intrahepatic biliary tree was
ilated with the use of a high-frequency, wave-
utting knife to facilitate stone removal. Com-
lete intrahepatic stone removal was accomplished
n two patients after the performance of 28 and
postoperative choledochoscopies, resp.; in these
ases, multiple stones were held back behind the
tricture in the biliary tree. In two other pa-
ients, only two and four postoperative choledo-
oscopies, resp., were necessary; in these cases,
tricture in the biliary tree was not seen. In
ly two of these four cases was a correct diagnosis
intrahepatic stones made by endoscopic retro-
ade cholangiopancreatography preoperatively. In
e remaining two cases, the dilated intrahepatic
cts were impacted with multiple stones, and pre-
erative examination failed to disclose the
sion because of incomplete filling of the contrast
dium. In these cases, a correct diagnosis was
de by postoperative endoscopic cholangiography.

72 THE SYSTEMIC TREATMENT OF GALLSTONES.

(Eng.) Tompkins, R. K. (Univ. California
Los Angeles Sch. Medicine, Los Angeles, CA).
. *Surg.* 10:87-98; 1976.

A review of systemic treatment approaches for the dissolution of gallstones is presented. At present, cholecystectomy remains the only proven cure for gallstones, and systemic approaches that aim at reducing the proportion of cholesterol in bile relative to that of bile acids and phospholipids are experimental. Chenodeoxycholic acid, a primary bile acid, has been shown to produce gallstone dissolution in man, but reported side-effects (diarrhea, cramps, nausea, and transient and persistent serum transaminase elevations) and potential toxicities (liver damage and increased body cholesterol pools) have restricted the drug to investigative use. The administration of the phospholipid lecithin has also been shown to be effective in solubilizing human bile cholesterol. In a prospective, nonrandomized trial in which patients with radiolucent gallstones were fed 48 g commercial soybean lecithin daily for 2 yr while being maintained on a low-fat diet, the bile was less lithogenic, and cholesterol crystals that had been present before treatment disappeared from the duodenal bile of all patients after 8 months of lecithin administration. No symptoms developed in patients on this protocol, but the gallstones were unchanged in size at the end of 2 yr. No data pertaining to trials with a combination of chenodeoxycholic acid and lecithin have been reported. Phenobarbital, although ineffective when used alone, has been shown to aid gallstone dissolution in some patients on chenodeoxycholic acid therapy. Florantyrone (Zanchol), a synthetic hydrocholeretic that does not have the usual gastrointestinal side-effects of bile salts, may also be capable of reducing cholesterol saturation in human bile, according to a recent report.

6573 THE ETIOLOGY AND PATHOGENESIS OF GALLSTONES.

(Eng.) Small, D. M. (Dept. Medicine and Biophysics, Boston Univ. Sch. Medicine, Boston, MA). *Adv. Surg.* 10:63-85; 1976.

The etiology and pathogenesis of gallstones are reviewed. Human gallstones fall into two chemical categories: those composed of bile pigments or their derivatives and those composed primarily of cholesterol. Pigment stones form when excess unconjugated bile pigments or their derivatives are present in bile and precipitate to form insoluble polymer-like complexes with calcium and copper. Although little is known of the etiology of pigment stones, it is suggested that patients with increased pigment production, such as those with severe chronic hemolytic anemia, will tend to get pigment stones. Patients with cholesterol gallstones generally have a bile containing excess cholesterol. Surgical gallstone disease is the end stage of a long process, starting with a genetic or metabolic defect and progressing through the stages of bile supersaturation, cholesterol precipitation, stone growth, and finally symptoms of gallstone disease. Possible etiologic mechanisms of cholesterol gallstone formation include: excessive cholesterol bile salt loss; oversensitive bile acid feedback mechanisms in which low rates of hepatic return of bile salts are adequate to depress bile acid synthesis; excessive cholesterol secretion;

mixed defects involving decreased bile salt secretion rate and a high cholesterol secretion rate; rapid bile salt circulation with decreased bile salt pool size; and primacy disorders of the gallbladder, bile ducts, or sphincter of Oddi. Certain drugs also affect bile secretion and saturation. Chemical gallstone disease in estrogen users is reflected in a 2-2.5 times greater risk of surgically documented gallstone disease in women taking birth control pills or in women taking estrogens in the postmenopausal period.

6574 GREY-SCALE ULTRASONOGRAPHY IN THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE.

(Eng.) Taylor, K. J. W.; Rosenfield, A. T. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Arch. Surg.* 112(7):820-825; 1977.

The accuracy of grey-scale ultrasonography was assessed in 150 patients with cholestatic jaundice, studied prospectively. All patients had a diagnosis established by subsequent biopsy, autopsy, or surgery. Using the presence or absence of a dilated biliary tree as the criterion, the intrahepatic or extrahepatic nature of the jaundice was correctly differentiated in 145 patients, an accuracy of 97%. All 64 patients with intrahepatic jaundice were correctly identified. Five of the 86 remaining patients, each of whom had gallstones, were misdiagnosed. In 82 patients (54.7%), the specific etiology was diagnosed. Ultrasound is an accurate method for the evaluation of jaundice and appears to have a definite value as a screening procedure before proceeding to more invasive studies.

6575 THE VALUE OF ULTRASONIC B-MODE SCANNING IN THE DIAGNOSIS OF PERSISTENT JAUNDICE.

(Eng.) Armitstead, P. R.; Addison, N. V.; Follows, O. J. (Bradford Royal Infirmary, England). *Br. J. Surg.* 64(9):630-632; 1977.

The value of ultrasonic B-mode scanning in differentiating obstructive from nonobstructive jaundice and in providing information as to the site and nature of any obstructive lesion was investigated in 67 patients with persistent jaundice. The gallbladder was identified on scanning in 92.5% of the patients; in four of five patients in whom the gallbladder was not seen, previous cholecystectomy had been carried out. The gallbladder was enlarged in 31 of the 67 patients, and this was confirmed at laparotomy in 28. Gallstones were visualized in 27 patients, but these were confirmed in only 19; six cases were definite false-positives. Thirty-eight patients appeared to have dilated extra- and/or intrahepatic bile ducts on the sonar scan; this condition was confirmed surgically in 36. Calculi were identified in the gallbladder and/or the bile ducts of 15 of the 29 patients without dilated bile ducts. In a further two patients, filling defects of the liver were found, and both patients were later shown to have hepatic metastatic malignant disease. A correct diagnosis was obtained using ultrasonic B-mode scanning in 66% of the cases, and useful information was gained in 26%. The information obtained from scanning was misleading or of no diagnostic value in only 8% of cases. This simple and noninvasive technique is valuable in the definitive diagnosis of persistent jaundice and should allow earlier surgery in the obstructive cases.

6576 ERRORS IN THE DIAGNOSIS OF OBSTRUCTIVE JAUNDICE IN CHILDREN.

(Rus.) Khristich, A. D.; Antoshkina, E. P. (Dnepropetrovsk Medical Inst., Dnepropetrovsk, USSR). *Pediatriia (Mosk.)* (8):81-83; 1976.

In children, surgical diseases with concomitant jaundice are often misdiagnosed as infectious hepatitis. The first patient, an 8-yr-old girl, had an almost 6-yr history of paroxysmal abdominal pains. She was unsuccessfully treated for infectious hepatitis and later for lamblious cholecystitis. Laparotomy showed a cyst of the common bile duct. The patient underwent choledochoduodenostomy; at the time of follow-up examination (3.5 yr later) she was in good health. The second patient, a 3-yr-old boy, had a history of abdominal trauma. Two months after contusion of the abdomen, he developed jaundice, which was diagnosed as infectious hepatitis. Conservative treatment gave temporary and nonsignificant improvement (he had several recurrences) and he underwent surgery. Laparotomy showed enlarged (10 x 3 cm in size) gallbladder and commissures in the external bile ducts. The patient underwent dissection of the common bile duct and end-to-side choledochoduodenostomy; 2.5 yr later, he was in good health. The third patient, a 4-yr-old girl, was seen with enlarged liver, skin itch, jaundice, and colorless stool; the disease was diagnosed as infectious hepatitis. In spite of the treatment, her condition progressively deteriorated, and with provisional diagnosis of biliary peritonitis, she was subjected to surgery. Laparotomy showed a 6 x 6 cm tumor arising from the right liver lobe. She underwent removal of the tumor and fistula of the gallbladder.

6577 EVALUATION OF JAUNDICE: FINE-NEEDLE ASPIRATION LIVER CYTOLOGY AS A DISCRIMINATING TOOL.

(Eng.) Henriques, U. V.; Hasselstrom, K. (County Central Hosp., DK-4200 Slagelse, Denmark). *Dan. Med. Bull.* 24(3):104-108; 1977.

The pathogenesis of jaundice was evaluated by fine-needle aspiration liver biopsy in 35 patients. The cytological criteria for obstructive jaundice were: (a) cholestasis; (b) virtually undamaged liver cells intermingled with increased number of granulocytes; and, (c) increased amounts of proliferating biliary epithelium. In the 35 jaundiced patients, fine-needle aspiration of the liver disclosed 13 cases of obstructive jaundice, all of which were later verified by laparotomy or by autopsy. Among the 22 cases with the cytological diagnosis of nonobstructive jaundice, 2 were subsequently found to be obstructive jaundice. The predictive value of obstructive jaundice was 1.00. The predictive value of nonobstructive jaundice was 0.91. The sensitivity with respect to obstructive jaundice was 0.87, and the specificity was 1.00. Fine-needle aspiration liver cytology is reliable in the diagnosis of obstructive jaundice.

6578 VALUE AND SAFETY OF PERCUTANEOUS LIVER BIOPSY IN OBSTRUCTIVE JAUNDICE.

(Eng.) Spellberg, M. A.; Bermudez, F. (Michael Reese Hosp. and Medical Center, Chicago, IL). *Am. J. Gastroenterol.* 67(5):444-448; 1977.

Seven cases are presented to illustrate the usefulness of percutaneous liver biopsy as an adjunct to simple, inexpensive, and noninvasive laboratory tests in the differential diagnosis of jaundice. Liver biopsy had been considered dangerous to use because of possible leakage of bile in patients with jaundice secondary to extrahepatic blockage, and its usefulness was doubted. The authors note that, after careful clinical and biochemical examination, some cases still difficult to diagnose were candidates for biopsy. Good technique and patient selection were recommended, and histologic criteria to differentiate hepatitis from extrahepatic obstruction are presented. In over 100 percutaneous liver biopsies, no serious difficulties such as bile peritonitis, transpired. Percutaneous liver biopsy represents a middle ground between noninvasive techniques and techniques such as transhepatic retrograde cholangiography that may be employed in the differential diagnosis of jaundice.

6579 CONVERSION OF PERCUTANEOUS TRANSHEPATIC CHOLANGIODRAINAGE TO INTERNAL DRAINAGE IN OBSTRUCTIVE JAUNDICE.

(Eng.) Takada, T.; Uchida, Y.; Yasuda, H.; Kobayashi, S.; Sakakibara, N.; Hanyu, F. (Inst. Gastroenterology, Tokyo Women's Medical Coll., Tokyo, Japan). *Jpn. J. Surg.* 7(1): 10-17; 1977.

The conversion of percutaneous transhepatic cholangiodrainage (PTCD) to internal drainage for the purpose of rerouting bile back to the intestinal tract in obstructive jaundice is described. Usually, a guide wire is inserted into the bile duct through the PTCD tube and is allowed to pass through the bile duct stricture until its tip enters the duodenum. Thereafter, a polyethylene tube having several side holes is inserted over the guide wire until its tip reaches a point 10 cm or more into the duodenum. The tube is positioned so that the side holes are located both in the intrahepatic bile ducts above the stricture and in the duodenum. Usually the method can be performed safely about 1 week after PTCD, when the edema of the bile duct wall has subsided and when its resistance is restored to normal. The conversion of PTCD to internal drainage was successfully performed in 10 of 13 cases. Failures involved incorrect positioning of the side hole portion of the tube and excess bile discharge. In two cases in which bile discharge before the conversion to internal drainage was over 2,000 ml daily and in which internal drainage by a single lumen tube resulted in bile stagnation, the tubes were replaced with double lumen tubes, and no signs of bile stagnation appeared thereafter. Failures associated with incorrect tube positioning are likely to occur in cases in which the stricture is located in the upper part of the bile duct near the bifurcation. Possible complications of the procedure include perforation of the ductal wall with the guide wire and the obstruction of the pancreatic duct orifice by the inserted tube, which may lead to acute pancreatitis.

6580 EXTERNAL TRANSHEPATIC DRAINAGE IN OBSTRUCTION OF THE UPPER SEGMENT OF THE BILE DUCTS.

(Rus.) Gredzhev, A. F.; Mukhin, I. V.; Popandopulo, G. P.; Konoplia, P. P.; Mysnik, G. G. (Donetsk Medical Inst., Donetsk, USSR). *Khirurgiia (Mosk.)* (12):70-72; 1976.

From 1953, 2,230 patients underwent surgery for inflammatory lesions of the bile ducts. Of 305 patients subjected to repeated surgery, 42 underwent hepatico-enterostomy anastomosis, and 16 of these underwent transhepatic drainage. Indications for drainage were estenosis of previously performed anastomosis (12), complete external bile fistula (3), and extensive decubitus of the posterior wall of the common bile duct due to the concrement (1). All patients had a history of two-three reconstructive surgeries, and all of them had marked symptoms of cholangitis and obstructive jaundice. The authors emphasize that drainage of anastomosis should continue for at least 6 months; accidental removal of the drain on day 17 after surgery resulted in estenosis of hepaticoduodenostomy in one patient. Postoperatively, all patients were free from complications due to the drainage: two patients died of causes other than surgery, and one patient died of cholangitis 45 days later.

6581 DIAGNOSIS AND MANAGEMENT OF ABSTRUSE ABDOMINAL PAIN.

(Eng.) Freeman, J. B. (Univ. Iowa Hosp. and Clinics, Iowa City, IA 52242). *Chir. Gastroenterol.* 10(4):409-415; 1976.

The hypothesis that cholecystokinin cholangiography combined with duodenal bile analysis may be useful in preselecting patients with obscure right upper quadrant pain and normal oral cholecystograms who might benefit from cholecystectomy was tested. Sixty-one women and nine men were studied. The oral cholecystogram was repeated without fat stimulation, and 75 U of cholecystokinin were infused over 2 min. The gallbladder was observed fluoroscopically for quality and degree of contractions. Duodenal bile, collected by suction on a duodenal tube, was cultured and examined microscopically under polarized light. Abnormal results were obtained in 54 of the 70 patients as evidenced by reproduction of the clinical symptoms (21), less than 50% gallbladder emptying (22), or the presence of crystals, bacteria, or inflammatory cells in the duodenal bile (11).

Fifty-one patients had cholecystectomy. The results during a 3- to 48-month follow-up period (mean, 17 months) were excellent in 48, good in 2, and no improvement in 1 patient. It is concluded that cholecystokinin cholangiography is a useful technique for predicting the presence of two distinct forms of neuromuscular gallbladder disease not detectable by routine cholangiography. The duodenal bile must also be examined or a significant number of patients with occult cholecystitis, gallstones, or cholesterolosis will be overlooked.

6582 HEMOBILIA AS COMPLICATION OF BILIARY TRACT SURGERY. (Rus.) Danilov, M. V.; Togonidze, N. A. (A. V. Vishnevsky Surgical Inst., Moscow, USSR). *Khirurgiia* (7):82-85; 1977.

6583 THE DIAGNOSIS OF CHRONIC CHOLECYSTITIS IN CHILDREN. (Ukr.) Diakova, R. M.; Tverskaya, S. S. (Inst. Advanced Training for Physicians, Zaporozhye, USSR). *Pediatr. Akush. Ginekol.* (3):4-5; 1977.

6584 OBSERVATION OF GANGRENOUS CHOLECYSTITIS IN A 6-YEAR-OLD CHILD. (Rus.) Bolgov, D. F.; Soldatov, B. S.; Matveev, Yu. E. (Blagoveshchensk Medical Inst., USSR). *Klin. Khir.* (6):81; 1977.

GENERAL

6585 EOSINOPHILIC GRANULOMAS OF THE GASTROINTESTINAL TRACT. (Eng.) Hans, S. S.; Hans, B.; Lee, P. T.; Knights, E. M. (Detroit-Macomb Hosp. Assoc., Detroit, MI). *Am. Surg.* 43(8):512-516; 1977.

The cases of four patients with eosinophilic granulomas of the gastrointestinal tract are reported. The first three patients, a 42-yr-old man, a 55-yr-old woman, and a 44-yr-old woman, had eosinophilic infiltration of the stomach. The symptoms included epigastric pain and bleeding. Peripheral eosinophilia was present in two of these three patients. In all three patients, the submucosa was diffusely infiltrated, predominantly by eosinophils and sometimes by histiocytes, lymphocytes, plasma cells, endothelial cells, and fibroblasts. The fourth patient, a 30-yr-old man, had an eosinophilic granulomatous polyp of the ileum. He had a 3-yr history of intermittent abdominal pain and a 2-week history of melena. At laparotomy, a 4-cm diameter polyp was found in the terminal ileum. The appendix was adherent to the intussusception mass and was involved in an inflammatory process. The polyp was composed of highly vascular granulation tissue diffusely infiltrated by WBC, about half of which were eosinophils. The authors believe that eosinophilic granulomatous lesions of the gastrointestinal tract comprise a distinct clinical and pathologic entity that should be considered in the differential diagnosis of obstructing or ulcerating lesions.

6586 HYPEROXALURIA AS COMPLICATION OF INTESTINAL DISEASES. (Ger.) Ruge, W.; Kohler, J.; Fromm, H. (Medizinische Klinik, Podbielskistrasse 380, D-3000 Hannover, W. Germany). *Med. Klin.* 71(46):2028-2032; 1976.

Urinary oxalate excretion was measured in 75 patients with Crohn's disease, ulcerative colitis, chronic disease of the pancreas with exocrine pancreatic insufficiency, sprue syndrome, other malabsorption syndrome or after partial resection of the small intestine by the Hodgkinson and William's method. An increase in urinary oxalate excretion was found in patients with resected parts of the small intestine (43.7 mg oxalic acid/g creatinine), sprue, and other malabsorption syndromes. Patients who underwent resection of the colon showed a lesser increase in urinary oxalate excretion (24.1 mg/g). Of the 75 patients, 4 had urolithiasis and exhibited increased values of urinary oxalate excretion (27-36 mg/g creatinine). There was a significant correlation between urinary oxalate excretion and steatorrhea, as well as between urinary oxalate excretion and the length of the resected small intestine. A weak correlation was established between urinary oxalate excretion and the extent of vitamin B_{12} malabsorption. Malabsorption, especially as an increased resorption of urinary oxalate in the colon or small intestine, is an important cause of hyperoxaluria. A suggested therapy to prevent urolithiasis in cases of hyperoxaluria included: a special diet with reduced amounts of oxalic acid; a reduction in the amount of fat in the diet; and the administration of cholestyramine (4 g, q.i.d.).

6587 MORPHOLOGICAL AND FUNCTIONAL CHANGES OF THE MUCOSA OF THE SMALL INTESTINE IN PATIENTS WITH KIDNEY DISEASES OF DIFFERENT INSUFFICIENCY LEVELS AND IN HEMODIALYSIS PATENTS. II. COMMUNICATION: FUNCTIONAL DISORDERS OF THE SMALL INTESTINE. (Ger.) Sperschneider, H.; Stein, G.; Kunath, H. (Medizinische Klinik des Bereichs Medizin, Friedrich-Schiller-Universitat, Bachstr. 18, 69 Jena, E. Germany). *Dtsch. Gesundheitsw.* 32(1):17-22; 1977.

A direct correlation was established between renal insufficiency and pathological changes in the small intestine by lactose tolerance, fat, and iron resorption tests in 115 patients with chronic pyelonephritis and glomerulonephritis. Of the 110 patients who underwent lactose resorption tests, 80 had normal blood sugar values, while 30 patients demonstrated a low blood sugar level. With an increase in renal dysfunction, there was a significant increase in the number of patients showing low blood sugar levels. Long-term dialysis (3 times per week) significantly decreased the number of patients showing low blood sugar levels. Of the 112 patients who underwent fat resorption tests, 24% receiving dialysis treatment, and 67% receiving no dialysis treatment showed a continuous decrease in fat resorption. Of the 100 patients who underwent the iron resorption tests, 5 indicated elevated iron resorption activity, while all the rest had decreased iron resorption activity, depending on the stage of renal insufficiency. No change in iron resorption activity was evident when dialysis was applied. Histological examination of the mucose membrane of the small intestine showed fusion and atrophy of the fimbria and villi, as well as inflammatory changes of the mucose membrane associated with an increase in renal dysfunction.

6588 INTESTINAL TUBERCULOSIS (A REVIEW OF 31 CASES FROM NEW YORK CITY). (Eng.) Homan, W. P.; Grafe, W. R.; Dineen, P. (New York Hosp.-Cornell Medical Center, New York, NY). *Chir. Gastroenterol.* 11(1):91-94; 1977.

Experience with 31 cases of intestinal tuberculosis at one hospital during the past 44 yr was reviewed. Twelve cases were seen prior to the availability of streptomycin in 1946, and 19 cases were seen thereafter. The most frequent site of involvement was the ileum (84% of patients), followed by the cecum (52%), jejunum (19%), and ascending colon (16%). Twenty-eight patients (90%) had evidence of pulmonary involvement, and no other site of tuberculosis was demonstrable in only two (6%). The most common symptoms were gastrointestinal upset (83% of patients), abdominal pain (77%), weight loss (74%), change in bowel habits (58%), and fever (52%). The difficulty in establishing diagnosis was reflected by duration of symptoms for longer than 1 month prior to diagnosis in 77% of patients. Gastrointestinal x-ray studies may not be diagnostic, but strongly suggestive, of intestinal myobacterial disease in the presence of pulmonary tuberculosis. Other diagnostic possibilities include Crohn's disease and neoplastic processes. The importance of instituting immediate antituberculous chemotherapy was emphasized by the 67% mortality rate in the patients presenting before the availability of streptomycin and the 21% mortality rate in patients receiving appropriate drug therapy. Ileocecal disease in the presence of pulmonary tuberculosis suggests the presence of intestinal tuberculosis. In the United States, ileocecal disease without the demonstrable presence of another site of tuberculosis makes intestinal tuberculosis unlikely. Antituberculous chemotherapy is the treatment of choice and surgery should be reserved for patients in whom the diagnosis is in question or in whom intestinal complications may occur.

6589 THE EFFECT OF DIET ON INTESTINAL *Escherichia coli*. (Eng.) Bettelheim, K. A.; Cooke, E. M.; O'Farrell, S.; Shooter, R. A. (St. Bartholomew's Hosp., West Smithfield, London EC1A 7BE, England). *J. Hyg. (Camb.)* 79(1):43-45; 1977.

To assess the role of food as a source of fecal *Escherichia coli*, the feces of six healthy subjects were examined and serotyped. All stools were collected during a 4-week period in which the subjects ate only a sterile diet and during two 2-week periods before and after the sterile diet period, in which the subjects ate a normal diet. The 279 specimens yielded 2,659 isolations of *E. coli*; 142 different *E. coli* serotypes were found, which included 60 O antigens and 34 H antigens. A large number of the serotypes (109/142) was isolated only once from each subject. The number of serotypes per specimen was less during the sterile diet period and rose after this period to levels higher than previously; before the sterile diet the number of serotypes ranged between 0.82 and 1.71; during the sterile diet the number ranged between 0.22 and 0.91, and after the sterile diet the number ranged between 1.00 and 3.00. However, a number of serotypes were isolated for the first time during the period of sterile diet. The results support the view that normal food is a source of *E. coli* strains present in the bowel. The serotypes acquired during the sterile diet may have arisen as a result of antigenic variation.

6590 AN IMMUNOFLUORESCENT STUDY OF α-FETOPROTEIN. II. ITS SIGNIFICANCE IN SOME NONHEPATOMA PATIENTS. (Eng.) Saitoh, K.; Harada, H.; Harada, K.; Inoue, K. (Second Dept. Surgery, Tokushima Univ., Tokushima, Japan). *Eur. Surg. Res.* 9(2):113-121; 1977.

Alpha-fetoprotein (AFP) was investigated to elucidate its site of synthesis in six nonhepatoma patients (5 with various tumors and 1 with congenital biliary atresia). AFP levels fell temporarily after surgery and chemotherapy in two patients (ages 12 and 14 months). However, the AFP levels increased again in spite of further treatment and the patients died. Two other patients (ages 17 months and 43 yr) were asymptomatic after removal of primary tumors and were treated for metastatic lesions. One of the patients maintained normal AFP levels and is still alive; the other showed increased AFP levels after surgery and chemotherapy and died of massive mediastinal and retroperitoneal recurrence. A common papillary projection in primary tumors was seen in five patients. Esophagogastrectomy resulted in a fall in AFP levels to within normal range, suggesting the gastric lesion as the main AFP producer in the adenocarcinoma patient (age 64 yr and still alive). The tumor cells from this patient showed prominent cellular and nuclear pleomorphism, and AFP was localized in their cytoplasm. Two operations of anastomosis between the liver and intestine caused AFP to fall in the patient with biliary atresia (age 1.7 months, died) but did not correlate with clinical features. A regenerative process of hepatocytes that were occasionally binucleated and that increased the thickness of liver plates was reported in this latter patient. AFP was of value in gauging the response to treatment or in predicting the outcome in tumor cases.

6591 SERUM GASTRIN RESPONSE TO ACUTE AND CHRONIC HYPERCALCAEMIA IN MAN: STUDIES ON THE VALUE OF CALCIUM STIMULATED SERUM GASTRIN LEVELS IN THE DIAGNOSIS OF ZOLLINGER-ELLISON SYNDROME. (Eng.) Lamers, C. B. H.; Van Tongeren, J. H. M. (St. Radboud Hosp., Univ. Nijmegen, Nijmegen, Netherlands). *Eur. J. Clin. Invest.* 7(4):315-317; 1977.

The effect on serum gastrin of calcium infusion over a 3-hr period without gastric aspiration was determined by radioimmunoassay in 15 normal subjects, 10 patients with duodenal ulcer, 9 with stomal ulcer, 5 with total gastrectomy, 6 with achlorhydria, and 16 with proved or presumed Zollinger-Ellison (ZE) syndrome. Serum gastrin rose significantly only in patients with ZE-syndrome or achlorhydria. An increase of above or below 50% of basal value seemed to be a useful criterion by which to differentiate between patients with and without ZE syndrome. In 44 patients with chronic hypercalcemia, serum gastrin levels (72 ± 24 pg/ml) were not significantly different from the levels in 100 normal subjects (66 ± 18 pg/ml, $p>0.10$). However, serum gastrin values were markedly higher during chronic hypercalcemia than during normocalcemia in one patient with ZE syndrome and in two patients with achlorhydria. It is concluded that acute or chronic hypercalcemia without gastric aspiration does not lead to hypergastrinemia in the absence of achlorhydria, or ZE syndrome.

GENERAL

Parasitology

6640 ELIEDA (ENZYME-LINKED-IMMUNO-ELECTRO-DIFFUSION-ASSAY): APPLICATION OF A COMBINED IMMUNOELECTRODIFFUSION AND IMMUNOENZYME METHOD TO THE STUDY OF IMMUNE RESPONSE IN PARASITIC INFECTIONS. (Eng.) Pinon, J. M.; Dropsy, G. (Hopital Maison Blanche, Reims, 51100 France). *J. Immunol. Methods* 16(1):15-22; 1977.

The technique of immunoelectrodiffusion (IED) has been combined with an enzyme method to enhance its sensitivity in determining immunoglobulins involved in antigen-antibody reactions. This combination constitutes the ELIEDA procedure (enzyme-linked-immuno-electro-diffusion-assay). ELIEDA is performed in three steps: (1) rapid formation of insoluble immune complexes by IED, (2) treatment of complexes with anti-heavy chain peroxidase-labeled antibodies, and (3) enzyme reaction to reveal sites of binding. The sensitivity of the method is equal or superior to that obtained by staining the proteins with Coomassie blue or amidoschwarz. In comparative tests on individual sera, as many as eight additional precipitating systems were revealed by ELIEDA that were not detectable by simple protein staining. The method was employed in studies of the immunology of parasitic infections, e.g., amebiasis, aspergillosis, schistosomiasis, filariasis, and hydatidosis. ELIEDA provides a valuable tool (sensitive and specific) for analyzing an organism's responses to complex immunogens.

6641 AMEBIASIS: AN INCREASING PROBLEM AMONG HOMOSEXUALS IN NEW YORK CITY. (Eng.) Schmerin, M. J.; Gelston, A.; Jones, T. C. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *JAMA* 238(13):1386-1387; 1977.

Two cases of amebiasis occurring in male homosexuals who had not traveled outside the New York area are presented, and the literature is reviewed. Both patients presented with nonbloody diarrhea with abdominal cramps. The stool cultures of both patients were positive for *Shigella flexneri*, as well as for *Entameba histolytica*. During a 5-yr period at one New York hospital, *E. histolytica* was identified in the stools of 20 men who had not traveled outside the New York area. All of these patients were homosexual. During this same period, amebiasis was diagnosed in 30 men who had traveled, and only 2 of these were homosexual. Of 10 patients with *E. histolytica* seen during the first year of this study, none were homosexual, whereas 8 of 11 patients in the fifth year were homosexual. This suggests the existence of a gradual increase of this disease among homosexuals.

6642 RADIOLOGY OF INVASIVE AMEBIASIS OF THE COLON. (Eng.) Cardoso, J. M.; Kimura, K.; Stoopen, M.; Cervantes, L. F.; Elizondo, L.; Churchill, R.; *et al.* (Dept. Radiology, Hosp. General Centro Medico Nacional, Mexico City, Mexico). *Am. J. Roentgenol.* 128(6):935-941; 1977.

The radiologic manifestations of invasive amebiasis of the colon caused by *Entamoeba histolytica* are described. The clinicopathologic forms, seen at the Hospital General Center Medico Nacional, Mexico, of this condition were ulcerative rectocolitis (95%), typhloappendicitis (3%), ameboma (1.5%), and fulminating colitis and toxic megacolon (0.5%). The barium enema was most informative, showing edema of the mucosa and mucosal irregularities in ulcerative rectocolitis and perforation and lateral pericecal compression from abscess in typhloappendicitis. The ameboma (segmental lesion) was characterized by a marked thickening of the bowel wall producing an excrescent mass that narrowed the intestinal lumen. The most reliable features of ameboma were multiplicity of the lesions, lack of shelving deformity, and rapid improvement with antiamebic therapy. The fulminating colitis followed a rapid, acute, toxic course and had a mortality rate of 90%. Various radiographic patterns were reported for this disease, e.g., nonspecific patterns, thumbprinting, toxic megacolon, perforation (in 60-87% of patients), fistula formation, and stenosis. It is suggested that this disease be included in the differential diagnosis of large bowel pathology even in nonendemic areas, since rapid progression and deterioration can occur if the diagnosis is delayed.

6643 AN EVOLVING PATTERN OF HUMAN HYDATID DISEASE TRANSMISSION IN THE UNITED STATES.

(Eng.) Pappaioanou, M.; Schwabe, C. W.; Sard, D. M. (Sch. Veterinary Medicine, Univ. California, Davis, CA 95616). *Am. J. Trop. Med. Hyg.* 26(4): 732-742; 1977.

The apparent association of human risk of infection with *Echinococcus granulosus* in the U.S. with particular population groups (Negroes in the southeast, Basques and Mormons in parts of the west) and occupations (backyard swine raising, transhumant sheep ranching) is reviewed. The 123 cases were analyzed by decade diagnosed, probable geographical origin of infection, sex, race, and age at diagnosis of the patients and organ site of cysts. Four percent of infections originated in the northeast, 24% in the southeast, and 53% in the west with the remainder unclassified by region. In the west, infection predominated in men, and in the southeast and northeast, it predominated in women ($p<0.05$). Fifty-one patients were reported to have had contact with dogs, 34 patients with sheep, and 3 patients with swine. Human populations now at risk in the western U.S. are transhumant sheep ranchers, including Basque-Americans in California, Mormons in Central Utah, and Navajo and Zuni Indians in New Mexico and Arizona. Highly favorable conditions to *E. granulosus* transmission, intensification, and spread exist in large areas of the western U.S. It is suggested that systematic surveillance and focal control programs for uniloculor hydatid disease be established in the U.S.

6644 COMPARATIVE SINGLE/DOSE TREATMENT OF HOOKWORM AND ROUNDWORM INFECTIONS WITH LEVAMISOLE, PYRANTEL AND BEPHENIUM.

(Eng.) Farid, Z.; Bassily, S.; Miner, W. F.; Hassan, A.; Laughlin, L. W. (U.S. Naval Medical Res. Unit No. 3, Cairo, Egypt). *J. Trop. Med. Hyg.* 80(5):107-108; 1977.

Levamisole, pyrantel, and bephenium were compared for their effectiveness in the treatment of hookworm and roundworm in 145 men (aged 7-45 yr) with *Ancylostoma duodenale* and or *Ascaris lumbricoides*. Fifty-one patients received a single 150-mg dose of levamisole, 47 received one 750-mg dose of pyrantel, and the remaining patients received one 5-g dose of bephenium. The percentage cure rates were 100% for ascaris and 93% for hookworm with levamisole, 90% for ascaris and 78% for hookworm with pyrantel, and 73% for ascaris and 81% for hookworm with bephenium. All drugs were well tolerated, but nausea and dizziness occurred in a few patients who received bephenium. The results show that the effectiveness of levamisole compares favorably with pyrantel and is superior to bephenium in the treatment of mixed hookworm and roundworm infections.

6645 IMMUNOLOGICAL STUDIES IN HUMAN SCHISTOSOMIASIS. III. IMMUNOGLOBULIN LEVELS, ANTIBODIES, AND DELAYED HYPERSENSITIVITY.

(Eng.) Camus, D.; Carlier, Y.; Capron, M.; Bina, J. C.; Figueiredo, J. F. M.; Prata, A.; *et al.* (Faculte de Medecine, Place de Verdun, 59000 Lille, France). *Am. J. Trop. Med. Hyg.* 26(3):482-490; 1977.

The present study was undertaken to establish a possible correlation between immunoglobulin levels, specific antibody titers, or delayed hypersensitivity (DHS) responses, and other biological or clinical parameters of infection by *Schistosoma mansoni* in a Brazilian population. Three groups of patients were studied: 1) untreated subjects (73) living in similar epidemiological conditions and regularly exposed to reinfection, 2) subjects not exposed to reinfection (34), and 3) surgically treated patients (26). Levels of IgG, IgE, IgM, and IgA were determined, specific antibodies were detected by the fluorescent antibody test, and hemagglutination tests, complement fixation tests, immunoelectrophoresis, and intradermal tests for DHS to *S. mansoni* antigens were done. The results were compared according to the clinical forms of the disease. IgG levels and antibody titers increased progressively in the subclinical, hepatomegalic, and hepatosplenic forms, and there was a statistical relationship between IgG levels and the intensity of responses to the four serological tests. DHS was found more frequently in hepatosplenic patients and more particularly in those with splenomegaly. DHS also correlated with age, but not with sex or skin color. The strongest DHS reactions were observed in patients 20-34 yr old, and in those having the highest fecal egg output. IgG levels, antibody titers, and DHS responses decreased after splenectomy and portal filtration of the worms. No significant variation in frequency of DHS was observed between untreated subjects, patients who were splenectomized, and a group not subject to reinfection for 4 yr.

6646 IgG DEPOSITS AND DISSE'S SPACE PATHOLOGY IN HUMAN SCHISTOSOMAL LIVER.

(Eng.) Grimaud, J. A.; Borojevic, R.; El Badrawy, N. (Centre de Microscopie Electronique, Institut Pasteur, 77, rue Pasteur, F-69365 Lyon Cedex 2, France) *Experientia* 33(8):1078-1079; 1977.

The mechanism responsible for the deposition of collagen in the space of Disse was investigated in liver biopsy specimens from patients with advanced Symmers' fibrosis associated with schistosomiasis. Electron dense deposits corresponding to peroxidase-labeled anti-IgG serum was observed in membranes of the vascular pole of the hepatocytes, inside the affected Disse's spaces, on both sides of the endothelial cells, and on the flocular deposits of the sinusoidal side of the endothelium. The demonstration of IgG deposits in the abnormal Disse's space demonstrates that immunological reactions are involved in the filling of these spaces in schistosomiasis.

GENERAL

Regional Enteritis

6671 LEVAMISOLE IN THE TREATMENT OF CROHN'S DISEASE. (Eng.) Segal, A. W.; Levi, A. J.; Loewi, G. (Clinical Res. Center, Watford Rd., Harrow, Middlesex HA1 3UJ, England). *Lancet* 2(8034):382-384; 1977.

The value of an elemental diet and levamisole in inducing and maintaining, resp., remission in Crohn's disease was studied in eight patients with active uncomplicated Crohn's disease. Clinical remission was induced in all patients with an elemental, protein-free diet. Improvement started 3-10 days after beginning the diet, and the patients generally became apyrexial during this period. Fourteen days after the start of the elemental diet, levamisole (50 mg, except for one patient in whom the dose was 25 mg) was administered every 8 hr for 3 consecutive days every 2 weeks. After the second course of levamisole treatment, the elemental diet was stopped and a normal diet resumed. The duration of this therapy has been 3-12 months. All patients responded, and seven are asymptomatic and leading normal lives. Arthritis was a side-effect in two patients, and this resolved when levamisole was withdrawn; one patient remains asymptomatic. Neutrophil migration into skin windows reverted to normal after treatment. The number of cells that entered the skin windows was significantly different from that in untreated patients with Crohn's disease ($p<0.001$) but similar to that in normal controls. Levamisole appears to be a useful drug in maintaining a clinical remission in Crohn's disease.

6672 CROHN'S DISEASE: RECURRENCE AFTER SURGICAL TREATMENT. (Eng.) Nygaard, K.; Fausa, O.

(Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 12(5):577-584; 1977.

Recurrence and reoperation rates are reported for a series of 76 patients who underwent surgery for Crohn's disease. In 14 patients, surgery was performed for recurrence after previous resection. A total of 93 surgical procedures were performed, with the most common being ileocolic resection (55 cases). The most frequent site of the disease was the terminal ileum or the terminal ileum plus the right colon (42 cases). There were four postoperative mortalities (5.3%) and four late deaths (1-6 yr after surgery). A statistical analysis of 66 patients who had undergone excisional surgery and had been followed up for a median period of 4.0 yr (range, 2-11 yr) revealed a yearly recurrence rate of 15.2% and a cumulative recurrence rate of 77% after 9 yr. The average yearly recurrence rate during the first 9 yr after surgery was 15.8% after primary operations and 13.8% after operations for recurrence; this difference was not statistically significant. The average yearly reoperation rate was 5.5%, and the cumulative reoperation rate after 9 yr was 45%. The rate of recurrence during the 1st postoperative yr was significantly ($p<0.01$) lower after radical resections (6/65) than after nonradical resections (8/15). These results corroborate those of other studies indicating that Crohn's disease has a great natural propensity to recur after surgical treatment. However, surgery does offer good palliation to many patients with serious symptoms.

6673 ISOLATION OF REOVIRUS-LIKE AGENTS FROM PATIENTS WITH CROHN'S DISEASE. (Eng.)

Whorwell, P. J.; Beeken, W. L.; Phillips, C. A.; Little, P. K.; Roessner, K. D. (Dept. Medicine, Univ. Vermont, Burlington, VT 05401). *Lancet* 1(8023):1169-1171; 1977.

Intestinal resection specimens from 10 patients with Crohn's disease and from 9 control specimens were examined for the presence of virus-like agents. Tissue homogenates were centrifuged at 10,000 x *g* for 1 hr, and passed sequentially through 1,200, 450, and 220 nm filters and cultured in WI-38 monolayers. Of the 10 Crohn's disease patients, 6 yielded an agent that produced a cytopathic effect in the WI-38 cells; none of the control specimens showed a positive reaction. Three of the six positive isolates were characterized. By filtration the virus was less than 220 nm and greater than 50 nm in diameter. Its growth was not inhibited by iododeoxyuridine, and it was heat-, ether-, and acid-stable. Electron microscopy revealed cored viral particles ranging in diameter from 55 to 60 nm. Aggregates of virus usually consisted of only a few particles. A 1/8 dilution of antiserum to Nebraska calf-diarrhea virus completely inhibited the development of a cytopathic effect by each of the three Crohn's disease isolates tested. The results suggest that this isolate belongs to the Reoviridae family.

6674 VARIABILITY OF SPLENOMEGALY IN CROHN'S DISEASE. (Eng.)

Rozen, P.; Flatau, E.; Schujman, E.; Gefel, A. (Ichilov Hosp., Weizmann St., Tel Aviv, Israel). *Am. J. Gastroenterol.* 67 (5):489-493; 1977.

The cases of five patients with Crohn's disease in whom splenomegaly was present are reported. The patients ranged in age from 14-67 yr, all men, and all were Ashkenazi Jews. In three febrile patients, splenomegaly was so prominent that the diagnosis of lymphoma was considered. Splenomegaly was an incidental finding in two patients and transient in one patient. Three patients also had hepatomegaly at some time during their course, although none had laboratory or biopsy evidence of significant liver damage. Splenomegaly is rare in Crohn's disease. Its presence may reflect the diffuse influence of this disease on the reticuloendothelial system, as manifested by the mesenteric lymphadenopathy commonly found in regional enteritis.

6675 FREE PERFORATION OF THE SMALL BOWEL IN CROHN'S DISEASE. (Eng.)

Croft, R. J. (Middlesex Hosp., Mortimer St., London W1, England). *Postgrad. Med. J.* 53(620):344-346; 1977.

A rare case of free double ileal perforation in previously asymptomatic and undiagnosed Crohn's disease of the terminal ileum is described. The patient, a 44-yr-old woman, presented with a 1-week history of generalized, intermittent, colicky abdominal pain associated with vomiting and constipation for the past 4 days. The abdominal examination revealed signs of generalized peritonitis. At operation, the terminal 32 cm of ileum showed typical features of chronic Crohn's disease, but without adhesions to other loops of bowel or abscess formation. On the antimesenteric border of the ileum, two free perforations were found 7 and 8.5 cm, resp., from the ileocecal valve. The remainder of the small bowel and the large bowel were normal. Primary resection of the terminal 42 cm of ileum, cecum, and proximal 10 cm of ascending colon was performed with end-to-end anastomosis. The patient remains well with no further evidence of Crohn's disease 19 months postoperatively. The absence of steroids in a previously undiagnosed case of Crohn's disease may favor primary resection and anastomosis.

6676 OBSTRUCTIVE UROPATHY IN CHRONIC INFLAMMATORY BOWEL DISEASE. (Eng.)

Fleckenstein, P.; Knudsen, L.; Pedersen, E. B.; Marcussen, H.; Jarnum, S. (Rigshospitalet, Blegdamsvej 9, DK 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12 (5):519-523; 1977.

A retrospective assessment of the frequency of ureteral obstruction in 140 patients with Crohn's disease and 88 patients with ulcerative colitis was performed on the basis of i.v. pyelography. The findings were related to x-ray examination of the gastrointestinal tract and to the clinical condition at the time of examination. The frequency of obstructive uropathy was 19% in patients with

Crohn's disease. Radiography of the gastrointestinal tract revealed a close topographic relationship between diseased areas of the bowel and the ureteral changes. Of 25 patients with right-sided hydroureter, all had radiological changes of the terminal ileum. Clinically, a mass in the iliac fossa was far more common ($p<0.01$) in patients with ureteral dilatation (24 of 26) than in patients without ureteral dilatation (34 of 114). A urinary-intestinal fistula was found in six patients, all of whom also had obstructive uropathy. Intestinal resection had been performed in 12 of the patients with ureteropathy, but the ureteral obstruction did not appear to be due to the operation. Among 88 patients with ulcerative colitis, 12 had ureteral obstruction. Colectomy had been performed in eight of these patients, and it seemed likely that six cases of ureteral obstruction were due to the colectomy. Patients with ureteral obstruction did not differ from other patients with ulcerative colitis with respect to clinical symptoms, urinary tract infection, or palpable mass. The use of i.v. pyelography is recommended before and after intestinal resection in chronic inflammatory bowel disease to demonstrate the relatively common and often fairly silent urinary tract complications.

6677 UROLOGICAL COMPLICATIONS OF REGIONAL ENTERITIS. (Eng.) Kruglik, G. D.; Neiman, H. L.; Sparberg, M.; Nudelman, E.; Mintzer, R. A.; Rogers, L. F. (Northwestern Memorial Hosp., Superior St. and Fairbanks Ct., Chicago, IL 60611). *Gastrointest. Radiol.* 1(4):375-378; 1977.

The cases of 37 patients with regional enteritis in whom excretory urograms were performed were reviewed to study the spectrum of radiographic findings and pathogenesis of urological complications in this disease. Urographic findings secondary to regional enteritis were observed in 21 cases; these included ureteral calculi (7 cases), retroperitoneal abscess (2), ureteral stenosis (5), panvesiculitis (4), and enterovesical fistula (5). Two major types of pathological processes may complicate regional enteritis and relate to the urinary tract. Metabolic derangements include the formation of renal calculi and the development of amyloidosis. Secondly, direct extension of the inflammatory process into the mesentery can result in retroperitoneal abscess formation, periureteral fibrosis with obstruction, or panvesiculitis with or without enterovesical fistula. In two of the four patients with panvesiculitis, a history of gastrointestinal symptoms was lacking, the urological abnormality thus revealing the extravesical disease prior to its clinical presentation. Routine and periodic excretory urograms should be a central part of the evaluation of patients with regional enteritis.

6678 POLYARTHRITIS AND CROHN'S DISEASE. REPORT OF ONE CASE. (Fre.) May, V. (Centre Hospitalier, 25, rue Pierre de Theilley, F 95500 Gonesse, France). *Rev. Rhum. Mal. Osteoartic.* 43(10):553-554; 1976.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing directly to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6679 DISTRIBUTION OF GASTRIN IN HUMAN, CANINE AND CAT DIGESTIVE TRACT DEMONSTRATED BY DIRECT IMMUNOFLUORESCENCE.

(Eng.) Henmi, K. (Kyoto Univ. Medical Sch., Sakyo-ku, Kyoto, Japan). *Arch. Jpn. Chir.* 46(1):18-37; 1977.

A highly specific direct immunofluorescent technique was used to determine the distribution of gastrin-containing cells in the digestive systems of humans, dogs, and cats, and to compare it among the three species. In all species, gastrin-containing cells were found only in the antrum and in the duodenum. The distribution within the duodenum, however, differed in humans from that in dogs and cats. In the human duodenum, gastrin-containing cells were seen in all portions from the pylorus to the third portion, in gradually decreasing concentration, while in the jejunum no gastrin-containing cells were seen. In the dog and cat duodenum, gastrin-containing cells were found only in the duodenal bulb, and none were seen distal to papilla of Vater. No gastrin-containing cells occurred in the esophagus, cardia, body of the stomach, jejunum, ileum, colon, pancreas, parotid gland, or submandibular gland in humans, dogs, or cats. The limits of distribution between the antrum and body of the stomach were sharply demarcated in all three species.

6680 SCANNING ELECTRON AND LIGHT MICROSCOPY OF THE CECUM OF GERM-FREE AND CONVENTIONAL MICE.

(Eng.) Geissinger, H. D.; Abandowitz, H. M. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario, Canada N1G 2W1). *Trans. Am. Microsc. Soc.* 96(2):254-257; 1977.

To compare the intestine of conventional and germ-free mice, the lumen of the cecum of mice was examined *en face* with the scanning electron microscope and cross-sections of certain areas were examined with the light microscope. Short stubby villi (not only crypts) were observed in the mouse cecum. These villi appeared shorter in germ-free than in conventional mice. The precise diagnosis of these findings was verified by light microscopy of the subsurface architecture of the intestinal segment. The microflora of the intestine of conventional mice contained some bacteria previously undescribed by scanning electron microscopy.

6681 ANGIOGRAPHIC RESEARCH ON COLONIC BLOOD SUPPLY WITH A VIEW TO ESOPHAGOPLASTY.

(Fre.) Popovici, Z. (15, rue Jutetului, bl. 17, sc. 2, ap. 41, Bucharest II, Rumania). *J. Chir. (Paris)* 113 (5/6):517-526; 1977.

For an angiographic study of colonic vessels, the colons (plus 15 cm of terminal ileum) of 34 cadavers were removed, and the arteries were injected with lead via the inferior mesenteric artery and the veins with a radiopaque barium suspension via the superior mesenteric vein. The 16 variants of the left colonic artery that were found were grouped into five main types. Variants of the sigmoid arteries and the left colonic veins were also identified. The colons were evaluated from the viewpoint of performing an esophagoplasty, and it was concluded that only 13/34 had good arterial vasculature for the procedure; 12/34 had fair vasculature. Of the 25 colon specimens with good or fair vasculature, the isoperistaltic transverse colon was better than the ileocolon in 64% and equivalent in 20%; the right ileocolon was preferable in 16%.

6682 ULTRASTRUCTURAL CHARACTERISTICS OF TUFT CELLS IN MOUSE GALLBLADDER EPITHELIUM.

(Eng.) Nevalainen, T. J. (Lab. Electron Microscopy, Univ. Turku, Turku, Finland). *Acta Anat. (Basel)* 98(2):210-220; 1977.

Tuft cells of mouse gallbladder epithelium were observed by electron microscopy after fixation in glutaraldehyde and/or osmium tetroxide, and the staining of thin sections with uranyl acetate and lead citrate. The tuft cells were infrequent and appeared triangular, with the broad base resting on the basal lamina and the apical surface reaching the gallbladder lumen. Uncomplicated lateral cell membranes and small, vertically oriented mitochondria differentiated the tuft cells from the columnar epithelial cells. The microvilli on the apical surface of the tuft cells were thicker and longer than the microvilli of the columnar cells. A heavy network of microfilaments extended from the core of the microvilli to the apical surface of the tuft cell and sometimes as far as the nuclear region near the basal cell surface. There were microtubules in the apical cytoplasm as well as many small vesicles. Only a few multivesicular bodies and dense bodies were observed throughout the cell. Unlike the columnar cells, tuft cells had sparse secretory organelles. Based on these results and the results of previous studies, possible roles for the tuft cells are discussed, particularly those of resorption and non-muscle cell organelle motility.

6683 EFFECTS OF CYTOCHALASIN B ON PANCREATIC ACINAR CELL STRUCTURE AND SECRETION.

(Eng.) Williams, J. A. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Cell Tissue Res.* 179(4):453-466; 1977.

The structure and function of pancreatic fragments, isolated acini, and isolated acinar cells from White Swiss mice (18-22 g) fasted overnight were studied by using cytochalasin B (CB). Structural change was elucidated microscopically and function tested by measuring amylase release. Krebs Henseleit bicarbonate media, equilibrated with 95% O_2-5% CO_2, was used. An additional 1% albumin was utilized in the media with acini and cells. CB inhibited bethanechol (3×10^{-5} M)-stimulated amylase release by fragments at 1 μg/ml or more, but had no effect on ATP content in the presence or absence of bethanechol. Adding the metabolic substrates pyruvate (4.9 mM), glutamate (4.9 mM), or fumarate (2.7 mM) did not alter the CB inhibition. Enlarged lumina were found with CB (5 μg/ml) alone under light microscope visualization or with CB (5 μg/ml) and bethanechol (3×10^{-5} M) together, utilizing either the light or electron microscope. CB (5 μg/ml) also caused the disappearance of microfilaments from the pancreatic fragments. Secretin (0.5 U/ml) acted similarly to CB, while cerulein (10 ng/ml) and CB combined produced results like those of bethanechol. CB (5 μg/ml) did not affect amylase release by isolated cells before or after bethanechol (10^{-4} M) incubation; however, CB did elicit zymogen granule marginization. Isolated acini incubated with CB and bethanechol showed luminal swelling and loss of microfilaments. It is suggested that inhibition of stimulated release may be due to disruption of acinar microfilament structure, but that the microfilaments may not be involved directly in secretion.

6684 DEVELOPMENT OF THE PANETH'S CELL POPULATION IN THE RAT. (Ger.) Linss, W.; Klett, U. (Anatomisches Institut, Friedrich-Schiller-Universitat, Teichgraben 7, 69 Jena, E. Germany). *Anat. Anz.* 140(5):494-497; 1976.

ABSORPTION - EXCRETION - TRANSPORT

6686 A STUDY OF AMINO ACID ABSORPTION FROM SMALL INTESTINES OF VINBLASTIN-TREATED RATS WITH ALTERED MUCOSAL MORPHOLOGY. (Eng.) Sharma, R. K.; Nagchaudhuri, J. (Inst. Medical Sciences, Banaras Hindu Univ., Varanasi, India). *Indian J. Med. Res.* 64(8):1225-1234; 1976.

Mitosis in the rat small intestine was arrested for various intervals with the alkaloid, vinblastine sulfate (VS) to investigate the influence of mitotic arrest on mucosal morphology and amino acid transport functions. Preliminary studies indicated that repeated i.p. injections of VS (1 mg/kg body weight) at 4-hr intervals could inhibit mitosis up to 24 hr. Histological studies on the small intestine of the treated animals revealed gradual changes in mucosal morphology commensurate with the duration of mitotic arrest. The villi showed a gradual decrease in total height and an increase in the diameter of the intervillous region, the loss of height of villi being due to the continual loss of cells of the crest region. There was also hyperplasia of goblet cells, shortening of the small intestine, and thickening of the muscularis. Intestinal absorption of L-proline, alone or in the presence of equimolar amounts of L-methionine, was studied by an *in vivo* sac technique in rats given 1, 5, 10, and 25 mg/kg doses of VS i.p. Rats from each group were used for absorption studies at 0.5, 8, and 24 hr following the injections. L-proline and/or L-methionine solutions (200 mM) were employed. The rate of L-proline transport was significantly decreased after four injections of VS (1 mg/kg, i.p.), approximately 16-18 hr after the first injection ($p<0.05$). Equimolar concentrations of L-proline and L-methionine given together decreased the effect of VS on L-proline transport; no reason for this effect could be advanced. Single injections of VS (10 or 25 mg/kg, i.p.) reduced L-proline transport to 80 and 50% of control values, resp., within 30 min. The effect of 25 mg/kg VS on L-proline transport may have been due to a direct toxic effect on the enterocytes, as this dose was lethal within 2-4 hr after its administration. However, lower doses were not obviously toxic, and L-proline transport inhibition at these doses may have resulted from a decreased surface area for absorption and loss of the fully differentiated absorptive cells at the villus tips. These results may elucidate the effect of protein calorie malnutrition (PCM) on intestinal amino acid transport since PCM also severely affects the rate of mitosis and the mucosal morphology in the intestine.

6687 COMPARATIVE EFFECT OF FOOD ON ABSORPTION OF AMPICILLIN AND PIVAMPICILLIN. (Eng.) Neuvonen, P. J.; Elonen, E.; Pentikainen, P. J. (Dept. Clinical Pharmacology, Univ. Helsinki, Helsinki, Finland). *J. Int. Med. Res.* 5(1):71-76; 1977.

The effect of food on the absorption of simultaneously ingested ampicillin or pivampicillin was compared in a crossover study in eight healthy women. The patients received either ampicillin (500 mg) or pivampicillin (350 mg) with water or with a test meal. The absorption of both ampicillin and pivampicillin was delayed by simultaneous food intake as judged by serum concentration and urinary excretion of ampicillin. The total absorption of ampicillin, but not that of pivampicillin, was decreased by simultaneous food intake, as indicated by the area under the serum ampicillin concentration-time curves and by 24 hr urinary excretion of ampicillin. The excretion of ampicillin into urine was about 30% of the dose when ampicillin was ingested with water into an empty stomach and about 20% when ingested with food. The respective excretion of ampicillin following the ingestion of pivampicillin was about 60% of the dose taken either with or without food. The more complete absorption, the lack of interaction with food together with diminished risk of superinfections seems to make pivampicillin preferable to ampicillin when a p.o. broad-spectrum, acid-stable penicillin is clinically indicated.

6688 ANION TRANSPORT IN BRUSH BORDER MEMBRANES ISOLATED FROM RAT SMALL INTESTINE.

(Eng.) Liedtke, C. M.; Hopfer, U. (Sch. Medicine, Case Western Reserve Univ., Cleveland, OH 44106). *Biochem. Biophys. Res. Commun.* 76(2):579-585; 1977.

The rates of anion transport in brush border membranes from the rat small intestine were measured *in vitro*. The addition of 15 µl of 1 M sodium salt solutions to 285 µl of a suspension of brush border membrane vesicles (6-7 mg protein/ml) caused a rapid release of protons, followed by a gradual re-uptake of protons and a corresponding anion translocation. Anion transport rates were calculated from changes in medium pH during reequilibration. To distinguish between molecular coupling and anion and proton transport by separate conductance pathways, the vesicles were preincubated with the proton carrier, carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone (CF_3-CCP, 3.4 nmol/mg protein). The relative rate constants of the uptake of acetate, chloride, nitrate, thiocyanate, and cyclamate in the absence of CF_3-CCP were 29.9, 9.8, 4.8, 3.9, and 0.08, resp. In the presence of CF_3-CCP, the rates of uptake of thiocyanate and nitrate were increased to 13.0 and 9.5, resp., which suggests that anions and protons are transported by separate conductance pathways. Since 49% of nitrate and 70% of thiocyanate transport occurred via a specific conductance pathway, the rate of thiocyanate transport in the absence of CF_3-CCP was considered the upper limit for endogenous proton conductance. The membrane appeared to be impermeable to cyclamate, since its slow uptake rate was not increased by CF_3-CCP. The rates of chloride and acetate transport without CF_3-CCP exceeded the limits for endogenous proton conductance, suggesting that 60% of chloride and 87% of acetate transport occurred via electroneutral transport systems with cations.

6689 TRANSMURAL IONIC FLUXES AND ELECTRICAL POTENTIAL DIFFERENCE IN THE HUMAN JEJUNUM DURING PERFUSION WITH A DIHYDROXY BILE ACID.

(Eng.) Oddsson, E.; Rask-Madsen, J.; Krag, E. (Herlev Hosp., Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(4):453-456; 1977.

Perfusion studies of the proximal jejunum were carried out in nine healthy subjects to define the influence of 2.5 mM glycochenodeoxycholic acid (GCDC) on the net movements of water and electrolytes, the bidirectional fluxes of ions, and the transmural electrical potential difference (PD). GCDC caused a significant ($p<0.01$) decrease in fluid absorption, the control net flux being +0.77 ± 0.13 ml/min, and the net flux after GCDC addition being -0.01 ± 0.16 ml/min. GCDC significantly decreased absorption or induced secretion of sodium, potassium, and chloride ($p<0.01$), but not bicarbonate; the levels before the addition of GCDC were +124 ± 20, +3.6 ± 0.6, and +31 ± 13 µmol/min, resp., and +5 ± 25, -0.3 ± 1.1, and -40 ± 16 µmol/min, resp., after the addition. In the control period sodium was absorbed against a small electrical gradient, while the chemical gradient was zero. The potential difference was 3 ± 1 mV, lumen negative, and was not influenced by GCDC. GCDC lowered the observed flux ratios (unidirectional flux from mucosa to serosa/unidirectional flux from serosa to mucosa) of sodium, potassium, and chloride. The results are consistent with a previously proposed model of the effect of GCDC, that is, inhibition of an active sodium pump at the basolateral membrane and a coupled, active sodium chloride influx process at the mucosal border.

6690 ACTIVITY OF CHLORIDE IN ABSORPTIVE CELLS OF Amphiuma SMALL INTESTINE.

(Eng.) White, J. F. (Dept. Physiology, Emory Univ., Atlanta, GA 30322). *Am. J. Physiol.* 232(6):E553-E559; 1977.

Double-barreled chloride-selective microelectrodes constructed by a new method were used to determine intracellular chloride activity (a^{i}_{Cl}) in the absorptive cells of isolated, stripped proximal and distal segments of *Amphiuma* small intestine. Chloride was passively distributed across the mucosal membrane in fall and winter animals and a^{i}_{Cl} is about 20 mM. In contrast, summer animals actively accumulated chloride in both proximal and distal segments. Parallel measurements of intracellular chloride concentration (C^{i}_{Cl}) revealed a very low apparent chloride activity coefficient (a^{i}_{Cl}/C^{i}_{Cl}), indicating that all of the chloride is not free in the cytoplasm. The chloride activity in the bath immediately adjacent to the mucosa was higher than in the bulk solution.

6691 ABSORPTION OF 'FORTIFICATION' IRON. BIOAVAILABILITY IN MAN OF DIFFERENT SAMPLES OF REDUCED Fe, AND PREDICTION OF THE EFFECTS OF Fe FORTIFICATION.

(Eng.) Bjorn-Rasmussen, E.; Hallberg, L.; Rossander, L. (Dept. Medicine II, Sahlgrenska Sjukhuset, S-413 45 Goteborg, Sweden). *Br. J. Nutr.* 37(3):375-388; 1977.

Absorption and bioavailability of "fortification" iron were studied to determine how well individuals on the borderline of Fe deficiency would absorb Fe from Fe-fortified meals and to define which physicochemical parameters predict the bioavailability of various forms of reduced Fe compounds. Dissolution rates of Fe compounds in HCl (pH 1), particle size in glycerol suspensions, and reactive surface area were measured. Two groups of 19 and 18 healthy volunteers (groups B and C) were fasted overnight and served two unfortified meals containing 2.4 mg intrinsic nonheme Fe(A) and two meals fortified with 4.0 or 11.3 mg ferrous sulfate (B and C, resp.) in the orders ABBA, BAAB, ACCA, and CAAC. ^{55}FeCl$_3$ (4 μCi) and ^{59}Fe (2 μCi) were added to the unfortified and fortified meals, resp. Retention of Fe at 2 weeks was measured in blood samples and by whole-body counting; the values were then compared to the retention 2 weeks later of ^{59}Fe from reference doses of ferrous ascorbate (3 mg Fe, 30 mg ascorbic acid). In addition, the absorption of four variants of a hydrogen-reduced, ^{55}Fe-labeled (3 μCi) Fe sample was studied by serving wheat rolls containing 0.5 mg of Fe compound and the extrinsic tracer ^{59}FeCl$_3$ (1 μCi) to four groups of healthy volunteers (2 rolls/subject). The dissolution rate and the reactive surface area of the various reduced Fe compounds were closely related, but the mean particle size was not always related to solubility. The ratios of Fe absorbed from fortified:unfortified meals increased from 0.26:0.13 mg to 0.87:0.17 mg for the meals fortified with 4.0 and 11.3 mg Fe, resp. The definite correlation between the amounts of Fe absorbed from the reference dose and the meal suggests that the effectiveness of Fe fortification in a population could be predicted by the knowledge of the population's Fe status. The amount of hydrogen-reduced Fe compound absorbed:amount of intrinsic Fe absorbed ranged from 0.13% to 0.90% and was directly related to the increasing dissolution rates. Dissolution rate and reactive surface are concluded to be better indicators of bioavailability than particle size.

6692 AN ANIMAL MODEL TO STUDY IRON AVAILABILITY FROM HUMAN DIETS.

(Eng.) Narasinga Rao, B. S.; Siva Prasad, J.; Vijaya Sarathy, C. (Indian Council Medical Res., Hyderabad-500 007, India). *Br. J. Nutr.* 37(3):451-456; 1977.

Iron retention from inorganic and organic sources was measured in guinea pigs, monkeys, and humans to determine whether guinea pigs or monkeys might provide a valid model for studying Fe absorption from human diets. Thirteen guinea pigs received, by stomach tube, 1 ml of a ferrous sulfate (^{55}FeSO$_4$) or a ferric chloride (^{59}FeCl$_3$) solution containing 0.5 mg Fe/m on 2 consecutive days. ^{55}FeSO$_4$ and ^{59}FeCl$_3$ were similarly administered to 12 monkeys in amounts that provided 1 mg Fe/kg body weight. Twelve days later, ^{59}Fe retention was measured by whole-body counting and by determining serum ^{59}Fe and ^{55}Fe activities. Rice- and wheat-based test meals containing tracer doses of ^{59}FeCl$_3$ (5 μCi, 10 μg Fe/μCi) were given to 29 humans and 12 monkeys. Fe retention was measured 12 days later by whole-body counting. The retention of ^{59}Fe from ferrous ascorbate at 3 mg Fe and 30 mg ascorbic acid was also determined after one of the diets was tested. The mean values of Fe retention (percentage administered dose expressed as the ratio ferric Fe: ferrous Fe were 7.0:8.6 in guinea pigs and 3.8:13.8 in monkeys. The ratio observed in monkeys was similar to that observed previously in humans. Monkeys absorbed less ^{59}Fe from ferrous ascorbate (12.2% administered dose) than humans (32.0%). ^{59}Fe retention from the rice- and wheat-based meals was lower in monkeys (1.9% and 0.98% administered dose, resp.) than in humans (6.1% and 1.50%, resp.). However, the absorption of Fe from food has been shown to be related to its absorption from inorganic sources. The retention ratios of food Fe:inorganic Fe (ferrous ascorbate) were similar in monkeys and humans (0.17% and 0.21%, resp., for the rice-based meal; 0.10% and 0.07%, resp., for the wheat-based meal). These results suggest that Fe retention values obtained with monkeys on human diets can be applied to humans after correcting for the differences in absolute amounts absorbed.

6693 EFFECT OF INTESTINAL MICROFLORA AND DIET ON SODIUM TAUROCHOLATE ABSORPTION IN THE RAT.

(Fre.) Riottot, M.; Sacquet, E.; Leprince, C.; Mejean, C. (Laboratoire des Animaux sans Germes du C.N.R.S., I.N.R.A., 78350 Jouy-en-Josas, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):621-624; 1977.

The gastrointestinal transit and ileal absorption rates of sodium taurocholate (NaTC) were measured in axenic and holoxenic rats fed either a commercial diet or a semisynthetic, semipurified diet consisting of 220 g casein, 580 g corn starch, 90 g corn oil, 50 g cellulose, and 45 g mineral salts. The gastrointestinal transit rate was lower (mechanical factor) and ileal absorption rate was higher in axenic rats than in rats with normal intestinal microflora. In both groups of rats, the quantity of intestinal NaTC was higher in rats fed the commercial diet than in those fed the semisynthetic diet of known composition. There was no significant difference in ileal absorption rate between axenic and holoxenic rats when both were fed the commercial diet. When lactose (10 parts/100 by weight) was added to the food or drinking water of holoxenic rats fed the semisynthetic diet, the ileal absorption of NaTC was increased along with the quantity of bile salts in the small intestine.

6694 INFLUENCE OF INTESTINAL MOTILITY ON WATER AND GLUCOSE ABSORPTION IN THE ANESTHETIZED RAT.

(Fre.) Legoux, M.; Lemaire, M. C.; Thouvenot, J. (Laboratoire de Physiologie, Faculte de Medecine, Universite de Tours, 2 bis bd Tonnelle, 37032 Tours Cedex, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):603-606; 1977.

The effect of intestinal motility on water and glucose absorption was studied in 31 anesthetized male rats. A tyrode solution containing glucose

(3 g/l) was infused into the stomach and duodenum of the rats by two methods: (1) the solution was pumped into stomach at a rate of 0.8 ml/min by a peristaltic pump or (2) the solution was kept in a reservoir under constant pressure (7 cm water), so that it entered the stomach at a spontaneous rate connected with intestinal motility. The amount of absorbed glucose relative to the total quantity introduced into the lumen was greater for the pumped infusion (0.30 ± 0.04% glucose; 0.12 ± 0.04% water) than for the spontaneous rate infusion (0.49 ± 0.10% glucose; 0.50 ± 0.08% water. It is concluded that mechanical conditions optimize intestinal absorption.

6695 FAT RESORPTION: CURRENT CONCEPTS AND MICROMORPHOLOGY. (Ger.) Gangl, A.; Pavelka, M.; Stockinger, L.; Grabner, G. (Ordinariat fur medizinische Computerwissenschaften und fur Gastroenterology, Universitat Wien, Garnisongasse 13, A-1090 Vienna, Austria). *Z. Gastroenterol.* 14(6):626-637; 1976.

MOTILITY

6697 ELECTRICAL STUDY OF MYOTOMY OF THE SMALL INTESTINE. (Fre.) Champault, G.; Legout, J.; Pourriat, J. L.; Patel, J. C.; Leger, L. (35, rue Ampere, 94400 Vitry-sur-Seine, France). *J. Chir. (Paris)* 113(3):311-318; 1977.

The effect of myotomy on the electrical activity of the rabbit small intestine was investigated. Control rabbits were subjected to an enterotomy of the same dimensions as the myotomy (equal or double the intestinal caliber). Electrodes were attached above and below the oblique incisions in rabbits premedicated with i.m ketamine and diazepam; electrodes were also implanted in three nonoperated rabbits. After 24-48 hr of decreased electrical activity, the amplitude of the electrical recordings above the functional obstruction increased, indicating increased peristalsis. These changes were observed in five of six rabbits during the first week. Recordings made up to 21 days after myotomy showed a gradual decrease in electrical activity, perhaps as a result of the technical conditions of the study. In animals subjected to enterotomy, electrical activity above and below the incision was identical after 24-48 hr of decreased activity, and it was similar to that observed in the nonoperated rabbits.

6698 AN INHIBITORY INNERVATION AT THE GASTRODUODENAL JUNCTION IN ANESTHETIZED DOGS. (Eng.) Mir, S. S.; Mason, G. R.; Ormsbee, H. S., III. (Univ. Maryland, Sch. Medicine, Baltimore, MD 21201). *Gastroenterology* 73(2):432-434; 1977.

The possible existence of an inhibitory innervation at the gastroduodenal junction (GDJ) was investigated *in vivo* in dogs. Motility induced by vagal stimulation was monitored with strain gauge force transducers on the gastric antrum, pylorus, and duodenum. The experiments were carried out in two phases: the control phase following vagotomy (TV), and the treated phase where atropine sulfate (1 mg/kg) was injected i.v. (TV + A). After TV, antral, pyloric, and duodenal contractile activity was significantly increased ($p < 0.01$) during the period of vagal stimulation. After TV + A, spontaneous activity in the antrum and duodenum was abolished and vagal stimulation did not increase motility in these organs. Spontaneous pyloric activity present after atropine administration was inhibited by stimulation, and a concomitant relaxation of the pylorus was also demonstrated. Following the termination of the stimulus, a significant increase in contractions was noted on the pylorus. These experiments demonstrate the existence of an atropine-resistant inhibitory innervation at the GDJ in the anesthetized dog.

SECRETION AND METABOLISM

6712 RELATIVE UTILIZATION OF AMINO ACIDS IN VARIOUS DIETS. A STUDY IN GROWING RATS. (Fre.) Mendes-Pereira, E.; Pion, R.; Prugnaud, J. (Laboratoire d'Etude du Metabolisme Azote, I.N.R.A., Theix, Saint Genes Champanelle, 63110 Beaumont, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4): 625-631; 1977.

To determine the effects of diet on the digestibility of amino acids (AA), weanling male Sprague-Dawley rats were fed a standard diet of 20% nitrogenous material for 6 days followed by one of several experimental diets for 7 days. The diets contained different proportions of wheat starch and carbohydrates, and they were balanced by the addition of synthetic AA. One casein diet had been heated to 90 C for 24 hr. The relative amounts of dietary, bacterial, and endogenous AA and nitrogen in the rat feces were computed. Except for the heated casein diet, the results indicated that the apparent decrease in the coefficient of utilization of nitrogen (CU-N) in the various diets was due generally to an increase in the excretion of bacterial and endogenous nitrogen. The highest CU-N was obtained in the casein-based diets (91.2), but it dropped to 82.8 when the diet was heated. The coefficient of utilization of total organic matter (CU-OM) in the diet was also measured. Diets with a high carbohydrate content had a high CU-OM and a low CU-N, which was attributed to the effect of the carbohydrates on bacterial protein synthesis (it increased with increase in microbial proteins excreted in feces).

6713 FECAL AMINO ACID COMPOSITION IN GERMFREE AND CONVENTIONAL RATS AND LAMBS. (Fre.)

Combe, E.; Pion, R. (Lab. d'Etude du Metabolisme Azote, I.N.R.A., Theix, Saint Genes Champanelle, 63110 Beaumont, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):633-636; 1977.

The dry matter, nitrogen, and amino acid (AA) composition of the feces of germfree (gf) and conventional (cv) lambs and rats was compared to determine the role of intestinal microflora in the digestion of nitrogenous matter of dietary or endogenous origin. The gf lambs were fed high-temperature-sterilized cow milk; the gf rats were fed a casein-based autoclaved diet that was hard to digest. Excretion of fecal dry matter and nitrogen was lower in the gf lambs than in the cv lambs, indicating greater milk utilization by the gf lambs; however, the reverse was true for gf and cv rats on the casein diet. To determine the reasons for this difference between the species, the AA composition of the milk, the casein diet, and the feces of the animals was analyzed. Sterilization apparently had little effect on the digestibility of the milk, and the utilization rate was high in both gf and cv lambs. This was demonstrated by the great difference in the AA composition of the milk and the feces. In contrast, excretion of fecal nitrogen from rats fed the hard-to-digest casein diet was increased in gf rats. The microflora might contribute to the digestion of dietary protein, thereby increasing nitrogen and AA digestibilities. Apparently, the effect of the microflora depends on the digestibility of the dietary nitrogen. The poor digestibility of the casein was demonstrated by the similar AA contents in the casein and the rat feces.

6714 ENDOCRINE AND METABOLIC RESPONSE IN THE HUMAN NEWBORN TO FIRST FEED OF BREAST MILK.

(Eng.) Aynsley-Green, A.; Bloom, S. R.; Williamson, D. H.; Turner, R. C. (John Radcliffe Hosp., Oxford OX3 9DU, England). *Arch. Dis. Child.* 52(4):291-295; 1977.

The hormonal and metabolic response to the first feed of breast milk was studied in 12 infants at 4-6 hr of age. After the feed, there was an increase in blood glucose concentration (fasting concentration 3.67 ± 0.22 mmol/l; mean increment at 55 min, 0.84 mmol/l) but no changes in the concentrations of lactate, pyruvate, alanine, or ketone bodies. The feed was followed by an increase in the concentrations of plasma insulin (6.8 ± 1.3 mU/l before, 15.3 ± 3.2 mU/l 55 min after feeding), growth hormone (17.7 ± 3.2 versus 27.8 ± 5.4 μg/l), gastrin (10.9 ± 1.3 versus 26.1 ± 1.9 pmol/l), and enteroglucagon (145.0 ± 30.0 versus 305.5 ± 64.8 pmol/l), but no change in levels of plasma glucagon or gastric inhibitory peptide. Several hormone systems are functionally active at birth and are stimulated by the first feed of milk.

6715 THYROID HORMONE CONTROL OF CYCLIC NUCLEOTIDE PHOSPHODIESTERASES AND THE REGULATION OF THE SENSITIVITY OF THE LIVER TO HORMONES. (Eng.)

Gumaa, K. A.; Hothersall, J. S.; Greenbaum, A. L.; McLean, P. (Dept. Biochemistry, Univ. Khartoum, Khartoum, Sudan). *FEBS Lett.* 80(1):45-48; 1977.

Thyroid hormone control of cyclic nucleotide phosphodiesterases and the regulation of the sensitivity of the liver to hormones was studied in male Wistar rats. Thyroidectomy significantly increased the activity of both low and high Km cyclic AMP phosphodiesterases (the former to an appreciably greater extent) of both the particle- and membrane-bound forms of the enzyme while having no effect on the two soluble forms. Thyroidectomy significantly increased the activity of the two cyclic GMP-phosphodiesterases of the soluble fraction while leaving the particle-bound forms unaffected. Thus, the contrasting intracellular sites for the regulation of cyclic AMP and cyclic GMP hydrolysis by thyroid hormone is apparent. The adenylate cyclase activity of the membrane fraction was increased by 40% following thyroidectomy, but no alteration was observed in the activity of the total particulate fraction. The changes in cyclic AMP- and cyclic GMP-phosphodiesterases in the livers of thyroidectomized rats parallel those previously found in adipose tissue in this condition. The similarity between these results on different tissues may point to a unifying hypothesis for the action of thyroid hormone on two major insulin- and glucagon-responsive tissues, liver and adipose tissue.

6716 EFFECTS OF GK-101 (NMG) AND SODIUM HYPOCHLORITE ON SALIVARY AMYLASE ACTIVITY.

(Eng.) Habib, C. M.; Kronman, J. H.; Goldman, M.; Cushner, S. (Tufts Univ. Sch. Dental Medicine, 136 Harrison Ave., Boston, MA 02111). *J. Dent. Res.* 56(6):665-669; 1977.

The effects of the sodium salt of *N*-monochloroglycine (NMG) and sodium hypochlorite on the activity of salivary amylase were studied in human saliva. Concentrations of each agent were varied to determine the concentration at which the threshold and total inhibition of enzyme would be obtained. NMG at concentrations of 0.10% (weight/volume) did not affect amylase activity, whereas sodium hypochlorite at concentrations of 0.05% totally inhibited salivary amylase activity. The results suggest that the use of sodium hypochlorite in the oral cavity should be limited; NMG, however, seems to be innocuous at concentrations 20 times those of sodium hypochlorite.

6717 THE INFLUENCE OF FIXATION ON THE CARBOHYDRATE CYTOCHEMISTRY OF RAT SALIVARY GLAND SECRETORY GRANULES. (Eng.)

Simson, J. A. V. (Medical Univ. South Carolina, Charleston, SC 29401). *Histochem. J.* 9(5):645-657; 1977.

The optimum fixation conditions for staining of carbohydrate-containing constituents of rat salivary gland secretory granules were investigated. In the parotid and submandibular salivary glands of the rat, the reactivity of secretory granules at both the light and electron microscopic level, with routine stains and with cytochemical reagents, was highly dependent upon the nature of the fixative employed. At the light microscopic level, secretory granules in rat parotid gland were PAS-positive if fixed with buffered formalin fixatives. However, if the gland was fixed with lipid-solvent-containing fixatives or with formalin at a very acid pH (as in Bouin's fixative), the PAS reactivity of the granules was lost. In the submandibular gland of rats, the acinar cells and granular tubules behaved similarly after such fixation in terms of their PAS reactivity, particularly in males; acinar cells of the female submandibular gland stained only lightly with PAS. At the fine structural level, the morphology of secretory granule constituents depended on the buffer used (cacodylate, phosphate, or collidine) and whether tissue was postosmicated. Postosmication considerably reduced the reaction of secretory granule components with stains for carbohydrates. The data indicate that the carbohydrate-containing components of both parotid and submandibular gland secretory granules are not typical long-chain neutral or acidic mucins, but are rather glycolipids or lipophilic glycoproteins that are solubilized by lipid solvents or at acidic pH and are lost or destroyed in the presence of strong oxidants.

SECRETION AND METABOLISM

Stomach

6722 RELATIONSHIP BETWEEN GASTRIC ACID SECRETION, HISTOPATHOLOGY, AND CELL PROLIFERATION KINETICS IN HUMAN GASTRIC MUCOSA. (Eng.) Hansen, O. H.; Johansen, A.; Larsen, J. K.; Pedersen, T.; Svendsen, L. B. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Gastroenterology* 73(3):453-456; 1977.

Cell proliferation of gastric antral and fundic mucosa was studied in 44 patients with different gastric diseases. After *in vitro* incubation of endoscopic biopsy specimens with ^{3}H-thymidine, radioautographs were prepared by the dipping technique. The labeling indices were estimated, and the specimens were classified according to the degree of gastritis. The peak acid output after "maximal" stimulation with histamine (40 μg/kg, s.c.) was also determined. A highly significant inverse correlation between peak acid output and the labeling indices in both antral and fundic mucosa was demonstrated. The correlation between the degree of gastritis and the labeling indices in antral and fundic mucosa was also statistically significant. The results indicate that a significant inverse relationship exists between the acid secretory capacity of the gastric mucosa and the rate of cell proliferation of both antral and fundic mucosa. The data suggest that an increasing degree of gastritis in human gastric mucosa is followed by an increased rate of epithelial cell proliferation.

6723 RAT GASTRIC MUCOSAL cAMP AND cGMP AFTER ADRENERGIC STIMULATION AND BLOCKADE. (Eng.) Ruoff, H. J. (Dept. Pharmacology, Univ. Tubingen, Wilhelmstrasse 56, D-74 Tubingen, W. Germany). *Eur. J. Pharmacol.* 44(4):349-354; 1977.

The effect of adrenergic stimulation and blockade on the concentration of cyclic AMP (cAMP) and cGMP was studied in the rat gastric mucosa. Epinephrine (0.5-2.0 mg/kg) elevated the gastric mucosal cAMP and cGMP levels up to 100% in a dose-dependent manner. Blockade of the β-adrenoceptors with propranolol (4 mg/kg) suppressed the effect of epinephrine on the cAMP level and increased the effect on the cGMP concentration up to 500%. The opposite effect was found under α-adrenoceptor blockade. Phenoxybenzamine (4 mg/kg) prevented the effect of epinephrine on the cGMP level and increased the effect on the cAMP concentration up to 300%. Predominant stimulation of the β-adrenoceptors by isoproterenol, or of the α-adrenoceptors by phenylephrine, caused smaller changes in the cyclic nucleotide concentration than did epinephrine. Their effect was more pronounced when the nonstimulated receptor was blocked. The data indicate that the rat gastric mucosa contains α- and β-adrenoceptors. The effect of epinephrine on the gastric mucosal cAMP level is mediated by β-adrenoceptors, and that on the cGMP level is mediated by α-adrenoceptors.

6724 A GASTROSCOPIC AND HISTOLOGICAL DOUBLE-BLIND STUDY OF THE EFFECTS OF DICLOFENAC SODIUM AND NAPROXEN ON THE HUMAN GASTRIC MUCOSA.

(Eng.) Lehtola, J.; Sipponen, P. (Univ. Central Hosp. Oulu, Oulu, Finland). *Scand. J. Rheumatol.* 6(2):97-102; 1977.

The effects of diclofenac sodium and naproxen on the gastric mucosa were studied in a double-blind trial by gastroscopy, gastrophotography, and histological examination of the mucosa in six healthy volunteers. Detectable lesions were evident in the mucosa of four subjects after the administration of diclofenac sodium (25 mg x 3, daily, 8 days) and after naproxen (250 mg x 2, daily, 8 days). The lesions were more extensive after the ingestion of naproxen than after diclofenac sodium in all of these cases. The most serious lesions verified by both gastroscopy and histology always occurred after exposure to naproxen. The histology of the gastric mucosa of two subjects with severe lesions showed spotty to moderate chronic superficial gastritis, whereas the overall histological appearance of the mucosa was normal in subjects with slight or moderate lesions after drug administration. The maximal acid output was positively correlated with the severity of the lesions. Subjective symptoms occurred in one person during diclofenac sodium and in three during naproxen administration.

6725 CHARACTERIZATION OF TWO MAJOR NEUTRAL GLYCEROGLUCOLIPIDS OF THE HUMAN GASTRIC CONTENT.

(Eng.) Slomiany, B. L.; Slomiany, A.; Glass, G. B. J. (New York Medical Coll., New York, NY 10029). *Biochemistry* 16(18):3954-3958; 1977.

The isolation of two major glyceroglucolipids (A and B) from a lipid extract of human gastric contents is described. The procedure involved column fractionation on DEAE-Sephadex, silicic acid, and thin-layer chromatography. Both glycolipids contained glucose, glyceryl ethers, and fatty acids. The structures of these glycolipids were identified by mild alkaline methanolysis, oxidation with periodate and chromium trioxide, and permethylation studies. It is proposed that glycolipid A is a monoalkylmonoacylglyceryl hexaglucoside and glycolipid B is a monoalkylmonoacylglyceryl octaglucoside. The diglyceride portion of these glycolipids consists mostly of 1-*O*-alkyl-2-*O*-acylglycerol.

6726 EFFECT OF LYSOLECITHIN ON GASTRIC MUCOSAL STRUCTURE AND POTENTIAL DIFFERENCE.

(Eng.) Orchard, R.; Reynolds, K.; Fox, B.; Andrews, R.; Parkins, R. A.; Johnson, A. G. (Charing Cross Hosp., London, England). *Gut* 18(6):457-461; 1977.

The effect of lysolecithin (100 mg%) on the guinea pig gastric mucosa was studied by instilling a solution for 30 min, preceded and followed by 0.1 N HCl into a total of 10 gastric pouches. Ten controls were instilled with HCl throughout. Lysolecithin produced a significant change in transmucosal potential difference (+8.5 mV, 23.3%), macroscopic erosions, and mucosal damage on histology and electron scanning microscopy. Eight of 10 stomachs showed multiple erosions, including acute hemorrhagic ulcers, after lysolecithin administration. There was focal and diffuse desquamation of the superficial mucosa with marked edema and loss of normal architecture after this treatment. None of these changes was seen in the control animals. The results suggest that the reflux of lysolecithin from the duodenum is an important factor in causing active gastritis and gastric erosions.

6727 SYNTHESIS AND GASTRIC ANTISECRETORY PROPERTIES OF 15-DEOXY-16-HYDROXYPROSTAGLANDIN E ANALOGUES.

(Eng.) Collins, P. W.; Dajani, E. Z.; Driskill, D. R.; Bruhn, M. S.; Jung, C. J.; Pappo, R. (Searle Lab., Chicago, IL 60680). *J. Med. Chem.* 20(9):1152-1159; 1977.

The preparation and gastric antisecretory activity of a series of 15-deoxy-16-hydroxyprostaglandin analogues are described. The compounds were tested i.v. in histamine-stimulated Heidenhain pouch dogs in relation to the reference standard prostaglandin E_1 (PGE_1) and PGE_1 methyl ester (PGE_1ME). The parent compound of this series, (±)-15-deoxy-16α,β-hydroxyprostaglandin E_1 methyl ester (3), was found to be equipotent to the reference standard PGE_1ME. Methylation at C-16 of 3 produced 8, which was found to be 40 times more potent than PGE_1. In contrast, the addition of two methyl groups to 3 at C_{15} or C_{17} markedly reduced the antisecretory action. The 16-ethyl analogue of 3 also showed reduced potency. Removal or epimerization of the C-11 hydroxy group of 8 reduced the activity. Hydrogenation or changing the stereochemistry of the 13,14 double bond from *trans* to *cis* decreased the activity. On the other hand, ω-homologation of 8 or the introduction of a *cis*-5,6 double bond did not affect the potency. It appears that 8, 16, and 17 possess optimum gastric antisecretory effects in this series.

6728 SEROTONIN DISTRIBUTION IN THE CANINE GASTRIC MUCOSA: ACUTE RESPONSE TO FEEDING AND POUCH PREPARATION. (Eng.) Hohenleitner, F. J.; Linguiti, C. M. (Temple Univ. Health Sciences Center, 3223 N. Broad St., Philadelphia, PA 19140). *Digestion* 15(6):506-516; 1977.

The gastric mucosa of anesthetized dogs was examined for serotonin (5-HT) in all major stomach regions. In dogs examined immediately after anesthesia induction, the proximal corpus or antrum had substantially more 5-HT than the pyloric canal, with concentrations for the dorsal and ventral proximal corpus, the antrum, and the canal being 2.58 ± 1.85, 1.96 ± 1.03, 1.87 ± 1.15, and 0.44 ± 0.39 µg/g, resp. Histological studies of two fasted and two fed dogs (one meal-fed and the other corn oil-fed) revealed a general pattern of declining enterochromaffin cell populations from the proximal corpus to the pyloric canal. When antral distention or digestive activity (corn oil feeding) was induced in different groups of dogs, only the latter produced a demonstrable, albeit transient, change in 5-HT. A 90% increase in 5-HT at 5 hr after oil feeding was observed in the ventral corpus; however, there was no change in 5-HT content in the corpus at 1, 3, or 7 hr after corn oil feeding. The 90% increase in 5-HT at 5 hr after oil feeding does not represent a substantial increase when compared to its potential for change, i.e., the 243% increase observed in gastric pouch dogs. In dogs prepared with gastric fistulas, a uniform distribution of 5-HT was found throughout the stomach after 0.4 ml/hr of neutral gastric juice was secreted for 4 hr.

6729 THE ACTION OF SEROTONIN ON BASAL GASTRIC SECRETION IN THE CONSCIOUS RAT AFTER INTRAVENTRICULAR AND INTRAPERITONEAL ADMINISTRATION. (Eng.) Bugajski, J.; Hano, J.; Danek, L.; Wantuch, C. (Inst. Pharmacology, Polish Acad. Sciences, Cracow, Poland). *Arch. Int. Pharmacodyn. Ther.* 225(1): 29-38; 1977.

The effects of serotonin (5-HT) and atropine, administered either i.p. or into the lateral cerebral ventricle (i.c.), upon gastric secretion in unanesthetized rats were studied to investigate the mechanism of 5-HT-induced inhibition of gastric secretion. The drug was administered after an 18-hr fast to 360 Wistar rats with chronic fistulas. Acid and pepsin outputs were determined hourly for 4 hr. Basal gastric secretion decreased dose-dependently in response to 5-HT (0.01-10 mg/kg, i.p.); a 10 mg/kg dose of 5-HT inhibited acid secretion up to 82% for 4 hr ($p<0.001$), and all but the smallest dose significantly decreased pepsin output. 5-HT (5-500 µg/rat) injected i.c. decreased acid output as much as 81% during the first hour, and some degree of inhibition (10-67%) persisted for 2-4 hr; the 1.0-µg/rat dose decreased pepsin output by 44.5%. Atropine administered i.p. (0.00001-0.5 mg/kg) also produced a dose-dependent decrease in gastric secretion and pepsin output, but had a more potent effect, requiring only 0.5 mg/kg to almost completely inhibit acid secretion for 3 hr, and 0.1 mg/kg decreased pepsin output by 37%. Atropine given i.c. at 100 µg/rat inhibited acid secretion 86% and caused a significant decrease in pepsin output. Reduction of secretory volume was the main cause of reduced acid secretion and pepsin output with both 5-HT and atropine. Acid concentration was decreased by large doses of the drugs, probably as a result of the depression of parietal cells of the gastric mucosa; pepsin concentration was not decreased by the drug concentrations employed in these studies. Atropine produced identical antisecretory effects when given by the two routes, whereas 5-HT had a stronger and faster action after i.c. than after i.p. administration. The latter difference is probably due to the blood-brain barrier preventing 5-HT from reaching the brain via the i.p. route. At large doses, however, 5-HT would cross this barrier, suggesting that its antisecretory action is partly central--via inhibition of ventromedial and hypothalamic structures.

6730 MECHANISM OF STRESS ULCER: INFLUENCE OF SODIUM TAUROCHOLATE ON GASTRIC MUCOSAL ENERGY METABOLISM DURING HEMORRHAGIC SHOCK AND ON MITOCHONDRIAL RESPIRATION AND ATPase IN GASTRIC MUCOSA. (Eng.) Menguy, R.; Masters, Y. F. (Univ. Rochester Sch. Medicine, 224 Alexander St., Rochester, NY 14607). *Am. J. Dig. Dis.* 21(12):1001-1007; 1976.

The effect of sodium taurocholate, which is known to aggravate stress ulceration, on gastric mucosal oxidative phosphorylation, ATPase activity, and energy metabolism during hemorrhagic shock in rabbits was studied to elucidate the relation between stress ulceration complicating hemorrhagic shock and shock-induced mucosal ischemia and energy loss. Oxidative phosphorylation and respiration were measured with and without taurocholate (125-1,000 µM) in a mitochondrial suspension derived from the corpus mucosa. At concentrations greater than 250 µM, taurocholate uncoupled oxidative phosphorylation in the suspension as judged by the increased basal rate of respiration (substrate but no ADP), the decreased ADP:O ratio, and the decreased respiratory control ratio. Gastric mucosal Mg^{2+}-dependent ATPase activity in the superficial and deep layers of the corpus mucosa was studied in cell homogenates from each layer in the presence of taurocholate (0-8.0 mM) with and without NaCl (100 mM) and KCl (30 mM); consistent differences between the two layers were found. Energy metabolism in the gastric mucosa during hemorrhagic shock was studied in rabbits fasted for 16 hr and then pylorus-ligated. Fifty milliliters of a solution containing H^+ (80 mEq/1), Na^+ (50 mEq/1), K^+ (10 mEq/1), and Cl^- (140 mEq/1) were instilled into the stomach with and without 30 mM taurocholate. Hemorrhagic shock was induced 20 min later by lowering the blood pressure to 30 mm Hg. After 15 min of shock, the stomachs were harvested by a "stop-freeze" method and the levels of ATP, ADP, AMP, and glycolytic intermediates were measured. ATPase activity in the superficial mucosal layer was enhanced by Na^+ plus K^+ but not affected by taurocholate alone; it was significantly reduced ($p<0.01$) in the presence of Na^+ plus K^+ and 8.0 mM taurocholate. In the deep layer, Na^+ plus K^+ slightly inhibited the ATPase activity; taurocholate (2.0-8.0 mM) significantly inhibited ATPase activity both with and without Na^+ plus K^+. *In vivo* treatment of the mucosa with taurocholate prior to hemorrhagic shock enhanced shock-induced dephosphorylation of nucleotides in the corpus and fundus mucosa and decreased the shock-induced acceleration of the glycolytic flux. It is concluded that the uncoupling of oxidative phosphorylation by taurocholate caused the enhanced breakdown of mucosal high-energy phosphate during shock. The results indicate that hemorrhagic shock-induced ischemia and reduced mucosal energy levels may produce gastric stress ulceration.

6731 OBSERVATIONS ON THE BEHAVIOUR OF BARIUM SULPHATE SUSPENSIONS IN GASTRIC SECRETION. (Eng.) Roberts, G. M.; Roberts, E. E.; Davies, R. L.; Evans, K. T. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff, Wales). *Br. J. Radiol.* 50(595):468-472; 1977.

See also, 6685, 6714, 6829, 6834, 6835, 6843, 6844, 6884, 6885, 6896, 6915, 6925, 6935, 7178.

6744 THE CHARACTERISTICS OF AMYLASE ACTIVITY AND THE ISOAMYLASE PATTERN IN SERUM AND URINE OF INFANTS AND CHILDREN. (Eng.) Otsuki, M.; Yuu, H.; Saeki, S.; Baba, S. (Kobe Univ. Sch. Medicine, Kusunoki-cho 7 chome, Ikuta-ku, Kobe, 650, Japan). *Eur. J. Pediatr.* 125(3):175-180; 1977.

Amylase activity and isoamylase patterns were determined in the serum and urine of 320 normal newborns, infants, and children. In the serum of newborns, measurable amounts of amylase were present. The activity increased with age and reached the normal adult level by approximately 8 months of age. Isoamylase analysis revealed that the low level of serum amylase in infants was mainly due to a deficiency in the pancreatic-type isoamylase. The absence of the pancreatic isoamylase in newborns and young infants is a physiological and developmental phenomenon. Great caution is therefore necessary when amylase isoenzymes are used in the diagnosis of abnormal pancreatic function, and such results must always be interpreted in relation to the age of the child.

6745 EFFECTS OF 16,16 DIMETHYL PROSTAGLANDIN E_2 ON FOOD-STIMULATED PANCREATIC SECRETION AND OUTPUT OF BILE IN MAN. (Eng.) Ekelund, K.; Johansson, C.; Nylander, B. (Karolinska Sjukhuset, S-10401 Stockholm 60, Sweden). *Scand. J. Gastroenterol.* 12(4):457-460; 1977.

The effect of 16,16 dimethyl prostaglandin E_2 (PGE_2) on food-stimulated pancreatic and biliary response was studied in seven healthy subjects, using a multiple indicator dilution technique. Despite significantly enhanced gastric emptying rate after the intragastric administration of 140 μg of the methyl analogue (0-20 min, $p<0.02$), the pancreatic and biliary responses were significantly decreased; the initial output rate of bilirubin was significantly lower after the administration of prostaglandin than in control experiments (0-20 min, $p<0.02$; 20-40 min, $p<0.05$), and the initial lipase output was significantly decreased after prostaglandin administration (0-20 min, $p<0.05$). The influence of 16,16 dimethyl PGE_2-induced inhibition of pancreatic and biliary output on normal digestion and absorption should be further investigated if this hormone is to be introduced as a drug in peptic ulcer treatment.

6746 EFFECT OF SECRETIN ON PLASMA MOTILIN IN MAN. (Eng.) Mitznegg, P.; Bloom, S. R.; Domschke, W.; Haecki, W. H.; Domschke, S.; Belohlavek, D.; *et al.* (Dept. Pharmacology, Univ. Erlangen-Nurnberg, D-8520 Erlangen, Universitatsstrasse 22, W. Germany). *Gut* 18(6):468-471; 1977.

The effect of secretin on motilin release was studied in six healthy men. Graded doses of 0.1, 0.3, 0.9, and 2.7 clinical U/kg/hr of pure synthetic secretin were infused over 60-min periods. Duodenal bicarbonate output and pH were recorded, and plasma secretin and motilin levels were measured by radioimmunoassay. During the infusions plasma motilin fell in a dose dependent manner to a nadir of 35%. This fall was linearly correlated with pancreatic bicarbonate output, whereas a nonlinear correlation was observed between plasma motilin and both plasma secretin level and duodenal pH. It is suggested that plasma motilin levels are decreased by secretin-induced pancreatic bicarbonate juice flow. This may be important for the control of motilin secretion initiated by duodenal acidification and the concomitant delay in gastric emptying.

6747 ACINAR CELL RESPONSIVENESS TO URECHOLINE IN THE RAT PANCREAS DURING FETAL AND EARLY POSTNATAL GROWTH. (Eng.) Larose, L.; Morisset, J. (Gastrointestinal Res. Unit, Sherbrooke Univ., Sherbrooke, Quebec, Canada). *Gastroenterology* 73(3): 530-533; 1977.

Studies were carried out to determine when, during fetal or postnatal life, rat pancreatic acinar cells acquire their capacity to respond to cholinergic drugs. The release of amylase, lipase, and chymotrypsin from Sprague-Dawley rat pancreas in response to urecholine was measured *in vitro*. Fetal and newborn pancreas did not respond to 10^{-5} M urecholine; 3- to 15-day-old pancreas demonstrated an increasing response to this dose. Peak sensitivity when compared to adult pancreas was present between days 15 and 21. These results indicate that the exocrine pancreas acquires a responsiveness to urecholine on the third day of postnatal life and becomes more sensitive to stimulation from the 15th day onward.

6755 MEASUREMENT OF LIVER BLOOD FLOW IN THE RAT USING AN ^{85}KRYPTON CLEARANCE TECHNIQUE. (Eng.) Rice, G. C.; Ryan, C. J.; Leiberman, D. P.; Mathie, R. T.; McGhee, E.; Harper, A. M.; *et al.* (Natalspruit Hosp., Transvaal, South Africa). *Br. J. Exp. Pathol.* 58(3):236-242; 1977.

A method for measuring liver blood flow (LBF) in rats was developed. The method involves recording the clearance of ^{85}Kr from the liver after the injection of a solution of the gas into the portal vein. This technique provides a measure of tissue perfusion at a cellular level. The animal preparation was maintained in a stable hemodynamic and respiratory state for up to 4.3 hr by careful fluid and anesthetic control. Stability of the model was reflected by relative constancy of the LBF measured throughout the experiment in all of the animals studied. The mean LBF determined in six rats was 2.41 ± 0.50 mg/g/min.

6756 THE EFFECT OF VASOPRESSIN ON HEPATIC ARTERIAL BLOOD FLOW. (Eng.) Simmons, J. T.; Baum, S.; Sheehan, B. A.; Ring, E. J.; Athanasoulis, C. A.; Waltman, A. C.; *et al.* (Massachusetts General Hosp., Boston, MA). *Radiology* 124(3):637-640; 1977.

The safety of directly infusing vasopressin into the hepatic artery was demonstrated by correlating changes in hepatic arterial blood flow with measurements of vasopressin blood levels in the canine hepatic vein, portal vein, and a systemic vein during the infusion of vasopressin into the hepatic artery, superior mesenteric artery, and into a systemic peripheral vein. The infusion of vasopressin (0.06 U/min) into the hepatic artery induced an average reduction in hepatic arterial flow of 75%. The flow increased rapidly after approximately 5 min, and it continued to rise, peaking at 45 ± 5.8% above base-line at 40 min. Superior mesenteric artery blood flow showed a prompt decline when the hepatic artery infusion was begun, stabilizing after approximately 15 min at 50% below the base line. The superior mesenteric artery blood flow increased as the infusion was terminated. When vasopressin was infused systematically and into the superior mesenteric artery, hepatic arterial flow showed a uniphasic rise. Infusion into the superior mesenteric artery resulted in the greatest rise in hepatic arterial flow (96.5%). The reduction in superior mesenteric artery blood flow was approximately the same with hepatic artery and systemic infusions, and 25% greater with direct superior mesenteric artery infusion. An inverse relationship was seen consistently between superior mesenteric and hepatic arterial blood flow. Superior mesenteric infusion produced a reduction in mesenteric blood flow of 70% and a rise in hepatic arterial blood flow of 96.5%. The results indicate that hepatic blood flow in the normal canine liver increases and is not compromised by a direct infusion of vasopressin into the hepatic artery.

6757 EFFECT OF STIMULATION OF HEPATIC NERVES ON HEPATIC O_2 UPTAKE AND BLOOD FLOW. (Eng.) Lautt, W. W. (Coll. Medicine, Univ. Saskatchewan, Saskatoon, Saskatchewan, S7N OWO, Canada). *Am. J. Physiol.* 232(6):H652-H656; 1977.

The effect of direct stimulation of the hepatic nerve trunk on oxygen uptake and hepatic hemodynamics was examined in cats. Acute denervation of the liver did not result in changes of oxygen uptake or hemodynamics in the intact liver. Stimulation of the hepatic nerves resulted in a marked reduction of vascular conductance of the hepatic artery and portal vein (intrahepatic) resulting in almost complete cessation of arterial flow and increased portal blood pressure. The hepatic artery showed a more complete escape from the neurogenic vasoconstriction than did the portal vein. During the stable "escape phase," oxygen delivery was 86% of control, but hepatic extraction of oxygen increased so that oxygen uptake was not altered from control values. The return of oxygen consumption to normal during nerve stimulation suggests that redistribution of hepatic blood flow did not occur. In spite of arterial and portal venous blood pressure changes and changes in gut conductance, oxygen extraction of the gut did not change.

6758 DIRECT MEASUREMENT OF ACTIVE TRANSPORT SYSTEMS FOR ALANINE IN FRESHLY ISOLATED RAT LIVER CELLS. (Eng.) Edmondson, J. W.; Lumeng, L.; Li, T. K. (Indiana Univ. Sch. Medicine, Indianapolis, IN 46202). *Biochem. Biophys. Res. Commun.* 76(3):751-757; 1977.

Alanine aminotransferase inhibitors, which block the metabolic utilization of alanine, were used in a method for the direct measurement of alanine transport in liver cells. Freshly isolated rat hepatocytes treated with 2 mM DL-cycloserine or 2 mM aminooxyacetate actively accumulated alanine in the medium by three neutral amino acid transport systems analogous to the Na-dependent alanine-preferring (A) and alanine-serine-cysteine (ASC) systems and the Na-independent leucine (L) system of Ehrlich ascites tumor cells. In a medium containing 1 mM alanine and 142 mM Na, cycloserine-treated hepatocytes accumulated alanine to a concentration six times that of the medium. Dinitrophenol (0.75 mM) inhibited this process totally. In Na-free medium containing 142 mM choline, intracellular alanine was only 1.5 times that of the medium. Thus, most of the active transport of alanine is Na-dependent. The contribution of the L system to alanine uptake was assessed by examining the effect of leucine on Na-independent alanine accumulation, and the contribution of the ASC system to hepatic alanine uptake was measured with the use of *N*-methyl-L-alanine, an amino acid solely transported by the A system. With 1 mM alanine in the medium, the contributions to total hepatic alanine accumulation of the A, ASC, and L systems were 60%, 20%, and 5%, resp. Passive influx accounted for the remainder of the hepatic alanine accumulation.

6759 ULTRASTRUCTURAL IMMUNOENZYMATIC STUDY OF α-FETOPROTEIN-PRODUCING CELLS IN THE HUMAN FETAL LIVER. (Eng.) Peyrol, S.; Grimaud, J. A.; Pirson, Y.; Chayvialle, J. A.; Touillon, C.; Lambert, R. (Centre de Microscopie Electronique et de Pathologie Ultrastructurale, Institut Pasteur de Lyon, 77, rue Pasteur, 69007 Lyon, France). *J. Histochem. Cytochem.* 25(6):432-438; 1977.

The ultrastructural characteristics of alpha fetoprotein (AFP)-producing cells were studied using an immunoenzymatic method. The cells in human fetal livers were stained using horseradish peroxidase. Ultrastructurally, three types of cells were identified: hepatocytes, biliary epithelial cells, and mesenchymatous cells. At low magnification, the AFP was seen in the cytoplasm of a small number of hepatocytes. These cells (type I hepatocytes) showed well-developed ergastoplasmic areas composed of numerous cisternae of rough endoplasmic reticulum arranged in parallel arrays. At higher magnification, the electron-dense AFP appeared to be localized on the membranes and on the ribosomes of this ergastoplasm. Glycogen was abundant in type I cells. Non-AFP-containing type II hepatocytes had poorly developed ergastoplasm. There was less glycogen in type II than in type I hepatocytes; the Golgi bodies were well developed, and numerous siderosomes and free ferritin particles were seen. The observations suggest that specific metabolic properties other than the presence or absence of AFP distinguish type I from type II hepatocytes.

6760 THE TRANSPORT OF BRANCHED-CHAIN AMINO ACIDS INTO ISOLATED RAT LIVER CELLS. (Eng.) McGivan, J. D.; Bradford, N. M.; Mendes-Mourao, J. (Dept. Biochemistry, Univ. Bristol, Bristol BS8 1TD, England). *FEBS Lett.* 80(2):380-384; 1977.

The uptake of L-leucine, L-isoleucine, and L-valine was studied in isolated rat liver cells. The strong temperature dependence of leucine uptake was showed by an arrhenius plot; at 0.5 mM leucine, the nonsaturable component accounted for less than 15% of the rate of uptake at 37 C. The plot showed a discontinuity at 18 C. The apparent activation energy in the range 4-18 C was 80.7 kJ/mol, while in the range 18-37 C the apparent activation energy was 32.6 kJ/mol. Leucine uptake was inhibited by the other two-branched chain amino acids and by methionine (each at 5 mM). The strong temperature dependence and the fact that leucine is inhibited by the other branched chain amino acids and by methionine indicates that at low concentrations, the kinetics of leucine uptake are mediated primarily by a specific transporting system in the inulin-impermeable cell plasma membrane. The uptake of isoleucine and of valine showed similar characteristics to that of leucine, and the apparent Km and Vmax values for the transport of all three amino acids were similar; the Km values for leucine, isoleucine, and valine were 5.5 ± 0.6 mM, 3.7 ± 0.8 mM, and 4.7 ± 0.8 mM, resp., and the Vmax values were 15.1 ± 2.3, 13.6 ± 3.2, and 13.5 ± 1.0 nmol/min/mg, resp. The data on the inhibition of the transport of these compounds were consistent with the postulate that leucine, isoleucine, and valine are transported with comparable facility on a common carrier system that is noncompetitively inhibited by methionine.

6761 UTILISATION OF AMINO ACIDS BY THE PERFUSED RAT LIVER. (Eng.) Hems, D. A.; Davies, M. G.; Thomas, A. J.; Whitton, P. D. (St. George's Hosp. Medical Sch., Cranmer Terrace, London SW 17 ORE, England). *Nutr. Metab.* 20(6):404-414; 1976.

Amino acid metabolism was studied in perfused Sprague-Dawley rat liver using a perfusate containing glucose; a mixture of glycerol, lactate, and pyruvate; and amino acids. Livers from fed rats utilized amino acids, especially when their initial concentration was higher than normal, despite the availability of carbohydrate in the perfusate and livers. Arginine, lysine, tyrosine, methionine, cystine, glycine, aspartic acid, histidine, and phenylalanine were rapidly removed by the liver; branched-chain amino acids were not released from the liver of fed rats. In perfusions of livers from starved or diabetic rats, amino acid uptake rates were generally faster than for fed rats. When perfusions were performed in which no amino acids were added to the medium, most of the amino acids normally occurring in blood appeared in the perfusion medium in the case of livers from normally fed animals; branched-chain amino acids appeared in the perfusate, indicating that lysis of endogenous protein was a major source of amino acids released into the perfusate. Livers from starved or diabetic rats released no significant quantities of amino acids, except branched-chain acids, which attained concentrations similar to those for fed rats. Thus, hepatic proteolysis in the absence of perfusate amino acids was not greatly increased by starvation or diabetes. Measurements of urea concentration in perfusate plasma revealed that in perfusions with four times the normal amino acid concentrations, the urea plasma concentration was 3.7 ± 0.5 mM for fed rats, compared with plasma urea concentrations of 6.1 ± 0.5 and 5.5 ± 0.6 for diabetic and starved rats, resp. From measurements of amino acids and urea in the perfusate, a balance of amino-nitrogen was calculated and showed that urea production exceeded amino acid uptake except in perfusions of livers of fed or starved rats where an excess of amino acids was present (four times normal levels, total initial amino-nitrogen concentration of about 16 mM). Thus, in the presence of an amino acid excess and an excess of available carbohydrate, livers from fed and starved rats maintained their protein content.

6762 INCREASED BILE ACID SYNTHESIS AFTER INTERRUPTION OF THE ENTEROHEPATIC CIRCULATION: EVIDENCE AGAINST HORMONAL MEDIATION. (Eng.) Hoffman, N. E.; Donald, D. E.; Hofmann, A. F. (Mayo Foundation, Rochester, MN 55901). *Proc. Soc. Exp. Biol. Med.* 154(1):49-52; 1977.

To determine whether a hormone is responsible for the striking increase in bile acid synthesis occurring after interruption of the enterohepatic circulation by ileal resection, experiments were carried out using an *in situ* perfused canine liver. Large dogs with ileal resections or sham operations were used as pump dogs to perfuse the livers from small dogs with sham surgery or ileal resection. Bile acid synthesis during 7 hr of observation was similar in livers in which sham-operated dogs and dogs with ileal resection were used for pumping. Since most known hormones act rapidly on the isolated perfused liver, the results suggest that a hormonal substance is not responsible for the increase in bile acid synthesis observed when the enterohepatic circulation is interrupted by removal of the ileum.

6763 REGULATION OF INTESTINAL UDP GLUCURONOSYLTRANSFERASE ACTIVITY BY FATTY ACIDS IN THE RAT. (Eng.) Hietanen, E.; Laitinen, M. (Dept. Physiology, Univ. Kuopio, PO Box 138, SF-70101 Kuopio 10, Finland). *Enzyme* 22(5):316-321; 1977.

The effect of individual fatty acids (elaidic and linoleic acids) on uridine diphosphate (UDP) glucuronosyltransferase (GT) activity was studied in the duodenal mucosa of adult male Wistar rats fed a standard diet, a fat-free diet, or a fat-free diet supplemented by 5% cholesterol. Elaidic and linoleic acids were administered i.p. at doses of 40 or 200 mg/kg every other day for 4 weeks. Mucosal UDP-GT activity was significantly increased by the fat-free diet (0.92 ± 0.06 nmol/min/mg protein, $2p<0.01$) and the fat-free, cholesterol-supplemented diet (1.01 ± 0.21 nmol/min/mg protein, $2p<0.05$) compared with the standard diet (0.55 ± 0.10 nmol/min/mg protein). Similar increases were noted when the diets were compared on a mucosal wet weight basis. At either dose level, elaidic or linoleic acid did not significantly alter the UDP-GT activity of rats fed the standard diet, but the administration of these unsaturated fatty acids to rats on the other two diets resulted in a lowering of mucosal UDP-GT activity to levels equal to or below those observed for rats fed the standard diet. It is suggested that essential fatty acids may control mucosal UDP-GT activity by regulating the microenvironment of the enzyme, since the protein content of a mucosal postmitochondrial supernatant remained constant during the experiment.

6764 BINDING OF BILIRUBIN AND LONG-CHAIN FATTY ACIDS TO HUMAN SERUM ALBUMIN WITH GENERAL REMARKS ON DISPLACEMENT OF FIRMLY BOUND LIGANDS. (Eng.) Brodersen, R.; Funding, L. (Inst. Medical Biochemistry, Univ. Arhus, Arhus, Denmark). *Scand. J. Clin. Lab. Invest.* 37(3):257-266; 1977.

Human albumin binding sites were evaluated to determine the effect of long chain fatty acids on primary and secondary affinities of bilirubin and to determine the parameters for the secondary binding of bilirubin to albumin. Free bilirubin concentration was quantitated by measuring its rate of oxidation with hydrogen peroxide and peroxidase monitored spectrophotometrically at 455 nm. Bilirubin/albumin complexes were studied by the shift in absorption at 470 and 430 nm at 25 C when bilirubin was bound to albumin. Studies with 0.5 mol bilirubin/mol albumin showed that oleate equal to 4 mol/mol albumin did not affect bilirubin binding to the high-affinity (first) site, while palmitate produced equivocal results. Marked spectrophotometric shift was noted with 2-3 mol bilirubin/mol albumin with saturation of secondary sites at approximately 4-5 mol. Most of the bilirubin was bound to the high-affinity site at a molar ratio of 0.5; when the ratio exceeded 1.0, the spectral change indicated binding to secondary sites. An equation was derived using the results obtained with human serum albumin containing natural fatty acids, with the defatted protein, and with 1 mol palmitate or oleate/mol albumin; it showed that secondary binding of 2 mol of bilirubin/mol albumin occurred with or without fatty acid addition. Spectrophotometric determinations of the secondary binding constants were carried out at 25 C, using the peroxidase method, relative measurements were made at 25 C and 37 C. The secondary binding of bilirubin to human serum albumin under physiological conditions may be described by two sites with an average binding constant of 5×10^{-5} l/mol. Free bilirubin concentration was calculated by an empirical equation that included the effects of various binding sites and that led to the suggestion that bilirubin may be displaced from the high-affinity site in icteric neonates, resulting in considerable increases in free bilirubin.

6765 IN VITRO EFFECT OF ASCORBIC ACID ON THE METABOLISM OF ADENINE NUCLEOSIDES AND NUCLEOTIDES IN THE LIVER OF RATS. (Eng.) Srivastava, U.; Theoret, G. (Departement de nutrition, Universite de Montreal, Montreal, Quebec, Canada). *Nutr. Rep. Int.* 16(1):81-88; 1977.

The *in vitro* effect of various concentrations of ascorbic acid on the metabolism of adenine nucleotides and nucleosides was studied in rat liver. A preincubation in the presence of ^{3}H-8-adenine allowed the labeling of a certain fraction of the cellular reserve of ATP. In the subsequent incubation, this radioactive nucleotide was hydrolyzed in part to give radioactive cyclic AMP (cAMP), 5'-AMP, and adenosine. Incorporation of radioactive adenine into ATP-ADP reached a maximum at two ascorbic acid concentrations (5 μg and 15-20 μg/ml incubation mixture). The accumulation of radioactive cAMP increased when the concentration of ascorbic acid was increased from 5 μg to 40 μg/ml. The accumulation of radioactive 5'-AMP increased considerably at 1-2.5 μg and at 20 μg ascorbic acid/ml. The accumulation of radioactive adenosine reached the maximum level at two concentrations of ascorbic acid (5 μg and 40 μg/ml). These results suggest that ascorbic acid stimulates the production of cAMP either by the enhanced protection in the formation of epinephrine, which potentiates adenyl cyclase to activate the formation of cAMP, or by direct competition for the active sites on cAMP phosphodiesterase. The data support the hypothesis that large quantities of vitamin C could be of value in the treatment of cancer, the common cold, hyperglycemia, and depressed mental state through the intervention of cAMP.

6766 METABOLISM OF 3α,7α,12α-TRIHYDROXY-5β-CHOLESTAN-26-OIC ACID IN NORMAL SUBJECTS WITH AN INTACT ENTEROHEPATIC CIRCULATION. (Eng.) Hanson, R. F.; Williams, G. C. (Dept. Internal Medicine, Univ. Minnesota, Minneapolis, MN 55455). *J. Lipid Res.* 18(5):656-659; 1977.

The formation of cholic acid from 3α,7α,12α-trihydroxy-5β-cholestan-26-oic acid (THCA) was studied in two normal subjects. [^{3}H]THCA and [^{14}C]cholic acid (6 μCi each) were administered i.v. by simultaneous injection, and the specific activities (percent injected amount/μmol) of [^{3}H]- and [^{14}C]cholic acid were measured in bile samples collected over a 5-day period. If the administered [^{3}H]THCA is rapidly and completely metabolized into cholic acid, the areas under the specific activity curves of [^{3}H]- and [^{14}C]cholic acid should be identical. In these two subjects, the area under the [^{3}H]cholic acid specific activity decay curves was only 18.4% and 9.0% less than the area under the [^{14}C]cholic acid specific activity decay curves. Thus, there is rapid and nearly complete metabolism of i.v. administered [^{3}H]THCA into cholic acid.

6767 EVIDENCE FOR THE LACK OF RESPONSE OF TYROSINE AMINOTRANSFERASE TO DIBUTYRYL CYCLIC AMP IN REGENERATING RAT LIVER. (Eng.) Hoshino, J.; Skiello, G.; Kuhne, U.; Kroger, H. (Robert Koch-Institut des Bundesgesundheitsamtes, Abt. Biochemie, Nordufer 20, 1000 Berlin 65, Germany). *FEBS Lett.* 79(2):409-412; 1977.

The response of tyrosine aminotransferase (TAT) to dibutyryl cyclic AMP (DBcAMP) was investigated in regenerating Wistar rat liver. The i.p. injection of DBcAMP (3 mg/100 g) 4 hr after 70% hepatectomy in nonadrenalized rats enhanced TAT activity 200% over the saline-treated control level. In contrast, DBcAMP elevated the TAT level only 60% in the adrenalectomized rats. After partial hepatectomy, TAT in the liver of adrenalectomized rats became entirely insensitive to the DBcAMP induction, although the basal enzyme level remained low. Administration of a noninducing dose of cortisone acetate (0.2 mg/100 g) together with DBcAMP markedly restored the response of TAT to the nucleotide inducer in the regenerating liver of adrenalectomized rats. TAT was readily induced by DBcAMP in nonregenerating liver slices from adrenalectomized rats. In contrast, TAT could not be induced at all by DBcAMP in slices from regenerating liver of adrenalectomized rats 18 hr after partial hepatectomy. The addition of a noninducing concentration of dexamethasone (1 nM) to the medium together with DBcAMP restored the response of the enzyme over the level of nonregenerating liver slices in a range of low DBcAMP concentrations. Since glucocorticoids do not affect the mitotic activity of the regenerating liver, the results suggest that the loss of the glucocorticoid-independent response of TAT to DBcAMP is characteristic of the proliferating cells or cells ready to proliferate.

6768 INHIBITION BY SOMATOSTATIN OF ADENOSINE-3', 5'-MONOPHOSPHATE STIMULATED HEPATIC RIBOSOMAL PROTEIN SYNTHESIS. (Eng.) Tragl, K. H.; Kinast, H.; Machanek, M. (I. Medizinische Universitats-Klinik, Lazarettgasse 14, A-1090 Wien, Austria). *Klin. Wochenschr.* 55(14):707-709; 1977.

The mechanism by which somatostatin inhibits ribosomal protein synthesis was studied in rat hepatocytes. Protein synthesis was unchanged when the liver cells were incubated with somatostatin (5 x 10^{-7} M) alone. However, cyclic AMP-stimulated ribosomal protein synthesis, polyU-directed polyphenylalanine synthesis, and polyribosome aggregation was prevented if somatostatin (1 x 10^{-7} M) was added to the incubation medium together with cyclic AMP. The results indicate that somatostatin inhibits the secretion of various pituitary and intestinal hormones by inhibiting AMP accumulation.

6769 ISOLATED RAT HEPATOCYTES AND 9000 g RAT LIVER SUPERNATANT AS METABOLIC SYSTEMS FOR THE STUDY OF THE PHARMACOKINETICS OF BARBITURATES. (Eng.) Yih, T. D.; van Rossum, J. M. (Dept. Pharmacology, Univ. Nijmegen, Netherlands). *Xenobiotica* 7(9):573-582; 1977.

Hepatocytes from overnight-fasted rats were isolated using collagenase, and a 9,000 x *g* supernatant of rat liver was used to study the pharmacokinetics and metabolism of barbiturates for comparison with published results based on isolated rat liver perfusion. Hepatocytes were incubated in 10 ml erythrocyte-Hanks Eagle solution (1:1, vol/vol), 15 ml hepatocyte suspension, and 5 ml barbiturate solution (10 mg/100 ml suspension buffer) at an oxygen tension of 60-80 mm Hg. Livers were homogenized and centrifuged (20 min) at 9,000 x *g* with incubation of the supernatant in 5 ml barbiturate solution plus 15 ml tris 0.05 M buffer, pH 7.4, containing an NADPH regenerating system. Barbiturates were analyzed using a gas chromatograph (GLC) with a nitrogen detector and metabolites were identified by GLC-mass spectrometry. Hepatocytes metabolized 5-ethyl-5-alkyl barbiturates at rates proportional to the length of the alkyl component, increasing up to the heptyl substituent. Only a few of the allyl and bromoallyl series barbiturates were metabolized. Barbiturates containing cyclic components were not significantly metabolized, while their *N*-methylated homologues were. Most of the 15 barbiturates investigated behaved similarly with respect to half-life and clearance rate when hepatocyte results were compared to liver perfusion investigations, except for methylheptabarbital. Barbiturate metabolism followed first order kinetics in the 9,000 x *g* supernatant assay system. Noctal, Talbutal, brallobarbital, methylbrallobarbital, and 5-ethyl-5-butyl barbituric acid were not appreciably metabolized. The data indicate that, for the majority of compounds tested, there are considerable differences in results between the 9,000 x *g* incubations on the one hand and the hepatocyte and liver perfusion incubations on the other. Samples from hepatocyte incubations could be resolved into hydroxy- and keto-metabolites, which was not possible with the 9,000 x *g* supernatant studies. The advantages of the hepatocyte suspension and liver homogenate preparation are compared. The isolated hepatocyte suspension appears to be an excellent system for the study of barbiturate metabolism.

6770 INHIBITION OF CARBON DIOXIDE FIXATION BY LEAD ACETATE IN RAT LIVER MITOCHONDRIA. (Eng.) Amatruda, J. M.; Staton, A. J.; Kiesow, L. A. (Naval Medical Res. Inst., Bethesda, MD 20014). *Biochem. J.* 166(1):75-79; 1977.

Studies were carried out in male Sprague-Dawley rats to determine the mechanism by which i.v. administered lead salts inhibit hepatic gluconeogenesis. Within 1 hr after the i.v. administration of lead acetate (10 mg), there was a 97% inhibition of CO_2 fixation in isolated rat liver mitochondria. This effect was concentration-dependent. The induction of phosphoenolpyruvate carboxykinase activity observed with starvation was also inhibited by i.v. administered lead acetate, but the activities of pyruvate kinase, glucose 6-phosphate dehydrogenase, and pyruvate carboxylase were unaffected, as was the oxidation of palmitate- and palmitoyl-coenzyme A by mitochondria from Pb^{2+}-treated animals. The addition of reduced glutathione to mitochondria from Pb^{2+}-treated animals had no effect on the inhibited CO_2 fixation. ATP concentrations in mitochondria from Pb^{2+}-treated animals were decreased, and the dose-response relationships for the effect of Pb^{2+} on CO_2 fixation and ATP concentrations corresponded. It is concluded that the decrease in mitochondrial ATP in Pb^{2+}-treated animals is probably responsible for the marked inhibition of CO_2 fixation, and hence the impairment of gluconeogenesis from alanine, lactate, and pyruvate observed by others.

6771 LACK OF TOXICITY OF CHENODEOXYCHOLIC ACID IN THE SQUIRREL MONKEY. (Eng.) Suzuki, H.; Yoshida, T.; Miki, H.; Sado, T.; Hashimoto, K. (Yamanouchi Pharmaceutical Co., Ltd., 1-8, Azusawa-1-chome, Itabashi-ku, Tokyo, Japan). *Gastroenterology* 73(2):310-313; 1977.

The toxicity of long-term administration of chenodeoxycholic acid was studied in squirrel monkeys of both sexes. The drug was administered p.o. to five groups of 26 animals each at a daily dose of 0, 10, 20, 40, and 80 mg/kg, resp., for a maximum of 52 weeks. No clinical symptoms that could suggest drug toxicity were observed. All laboratory studies (hematological; urinalysis for pH, protein, glucose, ketones, bilirubin, and urobilinogen; and liver function tests) were within normal limits. The proportion of lithocholic acid in biliary bile acids remained unchanged, whereas that of chenodeoxycholic acid was increased dose-dependently. No histopathological changes considered to be attributable to drug administration were observed.

6772 THE INCORPORATION OF Ga-67 INTO THE FERRITIN FRACTION OF RABBIT HEPATOCYTES IN VIVO.

(Eng.) Hegge, F. N.; Mahler, D. J.; Larson, S. M. (Veterans Admin. Hosp., Portland, OR). *J. Nucl. Med.* 18(9):937-939; 1977.

The relation between the metabolism of gallium and that of iron was studied on the subcellular level by comparing the incorporation of ^{67}Ga and ^{59}Fe into the ferritin fraction of rabbit hepatocytes *in vivo*. Twenty-four hours after the administration of ^{67}Ga citrate and ^{59}Fe citrate, the rabbits were killed and their livers removed and homogenized. Labile proteins in the filtered liver homogenates were denatured; ferritin was then crystallized from the supernatants by cadmium sulfate. Sephadex G-200 gel filtration of the ferritin fractions was carried out to determine the distribution of molecular weights in the substances associated with ^{67}Ga and ^{59}Fe. ^{67}Ga was found to be incorporated into the crystallizable ferritin fraction of rabbit hepatocytes with approximately one-sixth the uptake of simultaneously administered ^{59}Fe. Gel filtration chromatography confirmed that both the ^{67}Ga and the ^{59}Fe of the crystallizable ferritin fraction were associated with substances of the appropriate molecular weight for ferritin. Gallium appears to behave somewhat like iron in its interaction with ferritin, as it does in its interaction with transferrin and hemoglobin.

6773 EFFECT OF RETINOIC ACID UPON MEVALONIC ACID-2-^{14}C INCORPORATION INTO LIPIDS IN AN ISOLATED RAT LIVER FRACTION.

(Eng.) Erdman, J. W., Jr.; Elliott, J. G.; Lachance, P. A. (Dept. Food Science, 567 Bevier Hall, Univ. Illinois, Urbana, IL 61801). *Nutr. Rep. Int.* 16(1):37-46; 1977.

Methods were developed to study the effects of 400 μM retinoic acid (OIC) upon the timed incorporation of ^{14}C from 2-^{14}C-mevalonic acid into various lipids in the postmitochondrial supernatant fraction of rat liver. Liver fractions were incubated with various cofactors and mevalonic acid, with and without OIC, for up to 120 min. The reaction was stopped, lipids were separated with thin layer chromatography, the activities in bands were recorded, and Rf values were compared to various lipid standards. OIC depressed ^{14}C incorporation into cholesterol and cholesterol esters, while OIC increased ^{14}C accumulation into bands corresponding to fatty acids, mono-, di-, and triglycerides. OIC caused increased activity in squalene and in two other possible intermediates of cholesterol biosynthesis after 10 or 20 min incubation, suggesting that OIC initially inhibits cholesterol biosynthesis causing the build-up of intermediates. These results demonstrate that 400 μM OIC has a direct effect upon *in vitro* lipid synthesis in an isolated rat liver system.

6774 THE EFFECT OF THREE FORMS OF VITAMIN A UPON IN VITRO LIPOGENESIS FROM THREE CHOLESTEROL PRECURSORS.

(Eng.) Erdman, J. W., Jr.; Elliott, J. G.; Lachance, P. A. (Dept. Food Science, 567 Bevier Hall, Univ. Illinois, Urbana, IL). *Nutr. Rep. Int.* 16(1):47-57; 1977.

The effect of vitamin A on lipogenesis from ^{14}C-acetate (^{14}C-A), ^{14}C-mevalonic acid (^{14}C-M), and ^{14}C-isopentenyl pyrophosphate (^{14}C-IPP) was studied in perfused rat liver postmitochondrial supernatants. The incorporation of ^{14}C into lipid fractions after the addition of 4, 40, or 400 μM retinol (OL), retinyl acetate (YL), or retinoic acid (OIC) was monitored. All forms of vitamin A depressed ^{14}C incorporation of ^{14}C-A and ^{14}C-M into cholesterol. Only OIC depressed ^{14}C-IPP accumulation into cholesterol. OIC significantly increased incorporation of activity from ^{14}C-M and ^{14}C-IPP into the triglyceride fraction. Sodium deoxycholic acid increased ^{14}C-A but depressed ^{14}C-IPP incorporation into cholesterol. These results suggest that OL and YL act similarly, perhaps by inhibiting the conversion of ^{14}C-M to the ^{14}C-IPP. OIC may block a latter step such as the cyclization of squalene.

6775 ZONE ELECTROPHORESIS STUDY OF THE BILE LIPOPROTEIN COMPLEX.

(Eng.) Lafont, H.; Nalbone, G.; Lairon, D.; Dagorn, J. C.; Domingo, N.; Amic, J.; *et al.* (INSERM Groupe de Recherches sur le Transport des Lipides, 46, Bd de la Gaye, 13009 Marseille, France). *Biochemie* 59(5/6):445-452; 1977.

Bile was studied by zone electrophoresis to elucidate the interactions of phosphatidylcholines, bile salts, and polypeptides. Human bile was obtained from a T-tube in the common duct or by puncture of the gallbladder. The detergent form (biliary lipoprotein complex) was prepared using a gel column (Biorad A5m or Ultragel LKB ACA 34) equilibrated with taurocholate. Linear sucrose gradient electrophoresis was performed with a 5-30% (w/v) gradient. Isoelectric focusing was accomplished with 2% Ampholines, pH 3.5-10. Electrophoresis of native hepatic bile produced a single peak of phosphatidylcholines, two peaks of bile salts, and a cholesterol peak associated with the phosphatidylcholines. Four zones were found by isoelectric focusing. The first zone had many bands and contained 75% of the biliary albumin, while no protein was found in the second zone. The third zone was observed to contain 25% of the albumin, and the fourth zone possessed the phosphatidylcholines and little protein. The detergent form of the bile-lipoprotein complex gave a pattern on electrophoresis similar to native bile, except that the two intermediate peaks are sharply reduced. The electrophoretic pattern of a mixed micellar solution of bile salts was similar to that of native bile. Mixed micelles of phosphatidylcholines and bile salts produced an electrophoretically diffuse zone behind the bile salts. The detergent-free form, obtained without bile salt equilibration, showed on electrophoresis a single peak of phosphatidylcholines, which, on analysis, contained polypeptides (3% wt/wt). The delipidated polypeptides could be reassembled with deoxycholate and dilaurylphosphatidylcholine. It is suggested that the association of acidic polypeptides and phosphatidylcholines explains the high anodic migration of bile phosphatidylcholines.

6776 EFFECT OF DIETARY DI-2-ETHYLHEXYL PHTHALATE ON OXIDATION OF ^{14}C-PALMITOYL CoA BY MITOCHONDRIA FROM MAMMALIAN HEART AND LIVER. (Eng.) Bell, F. P.; Gillies, P. J. (The Upjohn Company, Diabetes-Atherosclerosis Res. Unit, Kalamazoo, MI 49001). *Lipids* 12(7):581-585; 1977.

The oxidation of 1-^{14}C-palmitoyl coenzyme A (CoA) by heart and liver mitochondria from male Sprague-Dawley rats fed dietary di-2-ethylhexyl phthalate (DEHP) was investigated *in vitro*. The oxidation of ^{14}C-palmitoyl CoA to $^{14}CO_2$ increased two- to threefold in hepatic mitochondria from rats fed 0.1% DEHP for 2-3 days; this increase appeared to be a maximum response, since similar data were obtained using hepatic mitochondria from rats receiving 0.5% or 1.0% DEHP in the diet. The response of hepatic mitochondria to DEHP continued throughout the duration of 35-day trials in which 1.0% DEHP was fed. In contrast to hepatic mitochondria, the oxidation of ^{14}C-palmitoyl CoA by heart mitochondria decreased approximately 40% upon addition of 0.1% or 0.5% DEHP to the diet; this effect of DEHP on heart mitochondria was not sustained beyond 8 days of DEHP feeding. Oxidation of ^{14}C-palmitoyl CoA was increased about twofold in hepatic mitochondria from rabbits fed 1% dietary DEHP for 12 days and in hepatic mitochondria from pigs that received 5 doses of DEHP (0.8 g/kg) at 12-hr intervals; the oxidation of ^{14}C-palmitoyl CoA by heart mitochondria from the same animals was unchanged in the rabbit but increased an average of 37% in the pig. DEHP feeding to rats was associated with increased yields of hepatic mitochondrial protein; standardized preparations of heart mitochondria were unaffected. The data emphasize the fact that phthalate esters are biologically active and capable of modifying lipid metabolism in mammalian systems.

6777 EFFECT OF DIETARY PROTEIN AND METABOLIC ACIDOSIS ON SERINE BIOSYNTHESIS IN THE KIDNEY AND LIVER. (Eng.) Nishida, T.; Fujisawa, Y.; Murakami, E.; Saito, M. (Ehime Univ. Sch. Medicine, Shigenobu, Ehime 791-02, Japan). *Nutr. Rep. Int.* 16(1):115-123; 1977.

The activities of enzymes involved in serine biosynthesis were assayed in the kidney and liver of Wistar rats that have been fed on diets containing various amounts of protein or starved for 2 days. The enzyme activities were also assayed in acidotic rat kidney and liver. The 3-phosphoglycerate dehydrogenase and phosphoserine phosphatase activities in the kidney were not affected by the protein content of the diet, whereas those in the liver were higher in rats on low-protein diets than in rats on high-protein diets. Starvation for 2 days did not affect 3-phosphoglycerate dehydrogenase activity in the kidney but decreased its activity in the liver about 50%. Metabolic acidosis decreased 3-phosphoglycerate dehydrogenase and phosphoserine phosphatase in the kidney but not in the liver. These results suggest that the phosphorylated pathway may play a role in serine biosynthesis in the kidney as it does in the liver, but that the regulations of this pathway in the kidney and liver may be different; in the kidney it may be regulated by acid-base balance, while in the liver it may be regulated by dietary stimuli.

6778 EFFECT OF ENDOTOXIN ON TRYPTOPHAN PYRROLASE AND δ-AMINOLAEVULINATE SYNTHASE: EVIDENCE FOR AN ENDOGENOUS REGULATORY HAEM FRACTION IN RAT LIVER. (Eng.) Bissell, D. M.; Hammaker, L. E. (Dept. Medicine, Univ. California, San Francisco, CA 94143). *Biochem. J.* 166(2):301-304; 1977.

Endotoxin was administered i.p. to rats at a dose shown previously to stimulate hepatic heme oxygenase activity and to block induction of δ-aminolevulinate synthase (1.5-2.0 mg/kg), apparently by causing redistribution of heme from cytochrome P-450 to a regulatory heme pool in the liver. Within 5 hr of the administration of endotoxin (at a time when the effect of the compound on cytochrome P-450 was maximal), the relative saturation of tryptophan pyrrolase with intrinsic heme rose, from a basal value of 50% to 90% indicating that "free" heme had become available. Concurrently, the activity of δ-aminolevulinate synthase was decreased to 25% of its basal value. Heme oxygenase reached peak activity 13 hr after endotoxin administration. These findings provide new evidence for the existence of an "unassigned" hepatic heme fraction, which exchanges with cytochrome P-450 heme and regulates these three enzyme functions.

6779 EXPERIMENTAL HEPATIC ENCEPHALOPATHY. CHANGES OF THE LEVEL OF WAKEFULNESS IN THE RAT WITH PORTACAVAL SHUNT. (Eng.) Beaubernard, C.; Salomon, F.; Grange, D.; Thangapregassam, M. J.; Bismuth, J. (Hopital Paul Brousse, 14, avenue Paul-Vaillant-Couturier, F. 94800 Villejuif, France). *Biomedicine* 27(4):169-171; 1977.

The level of wakefulness in Sprague-Dawley rats with portacaval shunt was evaluated by measuring the reactivity of the reticulocortical system by electrical stimulation of the brain stem reticular formation during slow wave sleep. The voltage level of stimulus necessary to provoke cortical awakening was significantly ($p<0.01$) decreased (by 30.7%) after portacaval shunt. The measurement of the reactivity of the reticulocortical system is a simple procedure that permits the quantitation of postshunt encephalopathy in the rat.

6780 REDUCTION OF GALLSTONE FORMATION BY ASCORBIC ACID IN HAMSTERS. (Eng.) Ginter, E.; Mikus, L. (Res. Inst. for Human Nutrition, nam. 4. aprilla 7, 88030 Bratislava, Czechoslovakia). *Experientia* 33(6):716-717; 1977.

The hypothesis that the formation of gallstones could be prevented by ascorbic acid was tested in hamsters. One hundred hamsters were fed a semi-purified, fat-free, high glucose, lithogenic diet containing 5 g ascorbic acid/kg for 6 weeks; 100 other animals received the same diet without ascorbic acid. Gallstone formation in the animals that received ascorbic acid (44%) was lower than that in the animals that received the lithogenic diet alone (88%). The animals on the ascorbic acid-containing diet also had a lower liver cholesterol concentration (582 ± 26 mg/100 g wet tissue) than did the controls (751 ± 49 mg/100 g, $p<0.01-0.001$) and a lower cholesterol half-life in the liver (16.3 versus 21.5 days, $p<0.01-0.001$) and in the plasma (15.7 versus 21.5 days, $p<0.01-0.001$). Cholesterol transformation to bile acids was increased in the animals fed ascorbic acid (2.53 ± 0.11 mg/14 hr/100 g) in comparison with the controls (2.16 ± 0.12 mg/24 hr/100 g, $p<0.05-0.02$). The results indicate that saturation of the liver with vitamin C significantly depresses the occurrence of gallstones in the hamster.

6781 EXPERIMENTAL INDUCTION OF HEPATITIS WITH CIRRHOTIC EVOLUTION IN THE RAT BY THE AMINO STEROID HOLAPHYLLAMINOL, OR AMINO-3-β-HYDROXY-20-β-PREGNENE-5.

(Fre.) Vu Ngoc Huyen; Choppin, J.; Desplaces, A.; Roux, G. (Centre de Recherche des Laboratoires Joullie, 20 bis, quartier Boildieu, 92800 Puteaux, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 284(13):1243-1246; 1977.

Holaphyllaminol (amino-3-β-hydroxy-20-β-pregnene-5) was administered by gastric intubation to male Wistar rats at doses of 50, 100, or 200 mg/kg/day for 10, 20, 40, or 80 days. Histologic examinations of the hepatic tissue revealed that all lesions originated in the periportal region. They started with cholestasis and canalicular proliferation, followed by a slowly progressing hepatocytic necrosis and parenchymatous fibrosis. These characteristic lesions, together with the absence of steatosis, mimic certain chronic active hepatites culminating in cirrhosis found in man. Since the severity of the lesions was linearly dependent on the dosage and duration of holaphyllaminol treatment, it may be possible to use this regimen to create a model for experimental chronic hepatitis.

6782 ALLEVIATION OF CARRAGEENAN-INDUCED HEPATOTOXICITY AND ACRONECROSIS BY APROTININ.

(Eng.) Fowler, E. F.; Thomson, A. W.; Horne, C. H. W. (Dept. Pathology, Univ. Medical Buildings, Foresterhill, Aberdeen AB9 2ZD, Scotland). *Br. J. Exp. Pathol.* 58(3):260-267; 1977.

The hepatotoxicity of carrageenan was studied in female LACA mice, and the effect of aprotinin on carrageenan-induced hepatotoxicity was investigated. Carrageenan (5 mg, i.p.) was found to be hepatotoxic. Raised serum transaminase activity after carrageenan administration was correlated with histopathological changes in the liver. These included necrosis of individual hepatocytes and focal areas of necrosis, with associated fibrin thrombi, 12 hr after carrageenan injection. Increased mitotic activity was observed at 72 hr and extramedullary hemopoiesis was noted at day 5. Acronecrosis, a further manifestation of intravascular coagulation, was evident within 24 hr of carrageenan injection, becoming clearly demarcated by day 5. Treatment with the anti-protease aprotinin (0.5 ml, i.p.) alleviated both the hepatotoxicity and the incidence and extent of acronecrosis induced by carrageenan. The possible mechanism underlying the *in vivo* toxicity of carrageenan and its alleviation by aprotinin is discussed in the light of these and other findings.

6783 ABNORMALITIES OF LIVER FUNCTION FOLLOWING EXTENSIVE JEJUNOILEAL BYPASS AND RESECTION IN RATS.

(Eng.) Hyland, G.; Stein, T.; Wise, L. (Washington Univ. Sch. Medicine, St. Louis, MO). *Surgery* 81(5):578-582; 1977.

Alterations in liver function and structure in the rat following a jejunoileal bypass were compared with those following jejunoileal resection to determine whether the retained excluded segment plays an etiological role in the deterioration of hepatic function in human patients who have undergone jejunoileal bypass. A greater than 90% jejunoileal bypass similar to the type performed in man for morbid exogenous obesity was performed in 70 adult female Wister rats; in an additional 70 rats, a greater that 90% jejunoileal resection was carried out. The control group consisted of 46 rats, which were not subjected to any experimental measures. Following operation, the bypass group demonstrated a significant ($p<0.02$) greater weight loss than did the resection group. Total plasma protein, albumin, and SGOT all decreased from the control in both the resection and bypass groups; the decrease, however, was more significant in the bypass than in the resected group ($p<0.05$ for protein, albumin, and SGOT in resected group; $p<0.001$, $p<0.005$, and $p<0.05$ for protein, albumin, and SGOT, resp., in the bypass group). These results suggest the possible production of a hepatotoxic factor in the excluded small bowel segment.

SECRETION AND METABOLISM

Intestine

6813 SPECIFIC INHIBITION OF CELL PROLIFERATION IN THE MOUSE INTESTINE BY AN AQUEOUS EXTRACT OF RABBIT SMALL INTESTINE. (Eng.) Sassier, P.; Bergeron, M. (Faculte de Medecine, Universite de Montreal, Montreal H3C 3T8, Quebec, Canada). *Cell Tissue Kinet.* 10(3):223-231; 1977.

Aqueous extracts from the mucosa of the rabbit small intestine were studied for their effect on DNA synthesis in the jejunum and proximal colon of rats *in vitro* and mice *in vivo*. The extracts were separated into two fractions by ammonium sulfate precipitation, the 0-50 fraction (F_1) and the supernatant (F_2). Everted rings of rat jejunum were incubated in the presence of ^{3}H-thymidine and F_1 or F_2 (protein content, 10 mg). Male mice were inoculated s.c. with 10 mg of F_1 or F_2 protein and then, at various intervals, with 4 μCi of ^{3}H-thymidine. The mice were killed 1 hr after thymidine injection, and 3-cm segments were removed from the jejunum and colon for analysis. The effect of the F_1 on cell-transit time in the mouse jejunum and colon was studied by inoculating mice s.c. with 4 μCi of ^{3}H-thymidine every 4 hr for 72 hr, and with 10 mg F_1 at 5, 9, and 13 hr after the initial thymidine injection. Three mice were killed 1 hr after each thymidine injection for analysis of DNA specific activity. The F_2 fractions did not have any inhibitory effect on DNA synthesis in either rats or mice. The Tris-HCl buffer and water F_1 fractions inhibited ^{3}H-thymidine incorporation into rat jejunal (66 ± 2.5% and 54 ± 3%, resp.), colonic, hepatic, and renal DNA. In mice, F_1 produced maximal inhibition of incorporation in the jejunal and colonic DNA within 2-4 hr. After 4 hr, F_1 reduced the specific DNA activity in the mouse jejunum and colon from control values of 27.6 ± 1.9 and 18.6 ± 1.9 disintegrations/min (dpm)/µg, resp., to 15.8 ± 2.4 and 10.4 ± 1.6 dpm/µg. This effect was reversible after 7 hr, which suggests that it was noncytotoxic. Cell-transit times were also increased by F_1. However, there was no significant inhibition of DNA synthesis in regenerating renal and normal adult testicular tissue. It is concluded that the F_1 fraction contains a chalone-like factor (or factors) that affects either DNA synthesis or the G_1-S transition of the cell cycle in the jejunum and colon of the mouse small intestine.

6814 INCREASED LEVEL OF cAMP IN THE RAT INTESTINAL MUCOSA CAUSED BY SODIUM LAURYL SULPHATE. (Eng.) Briseid, G.; Oye, I.; Briseid, K. (Inst. Pharmacy, Univ. Oslo, Blindern, Oslo 3, Norway). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(3):263-266; 1977.

The sodium lauryl sulfate (SLS)-induced increase in cyclic AMP in the jejunal mucosa of rats was studied. The level of cyclic AMP in the jejunal mucosa from tied loops of anesthetized rats was significantly increased (27-50%) when SLS (2-27 mM) was added to the loop fluid. Imidazole (25 mM) did not significantly alter the resting level of cyclic AMP, but reduced the increase caused by SLS (17 mM). Theophylline (25 mM) significantly ($p<0.001$) increased the intestinal level of cyclic AMP, and potentiated the increase caused by SLS. Ouabain (2.5 mM) did not alter the level of cyclic AMP in the presence or in the absence of SLS. The results of previous experiments on the increases in intestinal absorption caused by SLS or by dibutyryl cyclic AMP are discussed in light of the present data. It is concluded that the SLS effect on absorption can only partly be ascribed to its effect on the intestinal level of cyclic AMP.

6815 EFFECT OF DIETARY AMINO ACIDS AND FOOD INTAKE ON INTESTINAL SUCRASE AND LEUCINE-AMINOPEPTIDASE ACTIVITIES OF RATS. (Eng.) Kimura, T.; Shiosaka, S.; Sakakibara, A.; Matsuoka, A.; Yoshida, A. (Dept. Agricultural Chemistry, Nagoya Univ., Nagoya, 464 Japan). *Nutr. Rep. Int.* 14(6):657-670; 1976.

The effects of dietary amino acid deficiencies on intestinal sucrase (Su) and leucine aminopeptidase activities were studied by feeding male Wistar rats valine-, leucine-, lysine-, and protein-free diets, as well as 5% and 10% complete amino acid diets supplemented with sucrose, for 2 days. Rats were either force-fed three times daily at 4-hr intervals with 5 or 10 g of diet or fed *ad libitum*. The animals were sacrificed on the third day, their small intestines were removed, and the mucosa was scraped from the second 15-cm length of segment from the pylorus to the distal end. Force-feeding rats 10 g of the valine-free diet for 2 days decreased Su activity from 7.65 ± 0.78 U/mg protein (in rats force-fed 10 g of 10% complete amino acid) to 3.83 ± 0.66 U/mg. Su activities per unit weight of mucosa and per unit 15 cm length of segment were also significantly reduced. The protein-free diet also decreased Su activity, but to a lesser extent. Su activities per unit weight of mucosa or protein were significantly higher in groups receiving 5 g of valine-free, protein-free, or 10% complete amino acid diets than in those receiving 10 g. Changes in Su activities in rats force-fed the leucine- and lysine-free diets were intermediate between those in rats force-fed the valine-free and complete amino acid diets. There were no changes in Su activities per unit weight of mucosa or protein in rats fed the valine- and lysine-free diets *ad libitum*, but the segmental Su activities were significantly decreased from those observed in rats fed the 10% complete amino acid diet *ad libitum*. Changes in leucine aminopeptidase activity were similar but less-pronounced. Mucosal protein and segment weights of the small intestine, particularly that of the mucosa, were significantly reduced by the amino acid-deficient diets. The activities of intestinal enzymes are concluded to be influenced by the supply of amino acids to the mucosal cells.

6816 INFLUENCE OF BILE ACIDS ON THE (Na^+-K^+)-ACTIVATED- AND Mg^{2+}-ACTIVATED ATPase OF RAT COLON. (Eng.) Hafkenscheid, J. C. M. (St. Radboud Hosp., Univ. Nijmegen, Nijmegen, Netherlands). *Pfluegers Arch.* 369(3):203-206; 1977.

The influence of various bile acids on the (Na^+-K^+)-ATPase and Mg^{2+}-ATPase activity of rat colon was studied. At 0.6 mM, cholic acid (C) and taurocholic acid (TC) did not inhibit the (Na^+-K^+)-ATPase activity in contrast to glycocholic acid (GC). The taurine derivative taurochenodeoxycholic acid (TCDC), taurodeoxycholic acid and TC did not inhibit the (Na^+-K^+)-ATPase activity. All bile acids except C, TC, and chenodeoxycholic acid depressed the Mg^{2+}-ATPase activity. At higher concentrations, only C and TC did not influence the (Na^+-K^+)-ATPase activity. C, GC, and TC at 2.5 mM decreased the activity of the (Na^+-K^+)-activated phosphatase with ATP as substrate. All other substrates tested did not influence the enzymic activity significantly. The results indicate that bile acids can inhibit the Na^+-absorbing system in rat colon. This inhibition can cause diarrhea.

6817 ESTEROLYTIC ACTIVITIES OF RAT INTESTINAL MUCOSA. 1. CHARACTERIZATION, CELLULAR DISTRIBUTION AND SUBCELLULAR LOCALIZATION OF A GLYCEROL-ESTER HYDROLASE. (Eng.) Negrel, R.; Serrero, G.; Fernandez-Lopez, V.; Ailhaud, G. (Centre de Biochimie, Faculte des Sciences, Universite de Nice, Parc Valrose, F-06034 Nice-Cedex, France). *Eur. J. Biochem.* 71(1):249-258; 1976.

The cellular distribution and subcellular localization of a glycerol-ester hydrolase (GEH) isolated from the intestinal mucosa of male Sprague-Dawley, germ-free rats are described. The intestines were removed, the mucosal cells were collected, and subcellular fractions were prepared as required. The GEH (assayed titrimetrically with tributyrin) was not of pancreatic origin, as there was no cross-reaction between the hydrolase in a crude supernatant of intestinal cells and an immunoserum directed against the rat pancreatic juice. Contamination by pancreatic carboxyl-ester hydrolase or pharyngeal acidic lipase was excluded. A high level of GEH activity was found in the intestinal lumen. The cellular GEH activity decreased from 5,700 ± 500 mU/mg of protein at the villus tips to 3,000 ± 200 mU/mg in the crypt cells. Subcellular fractionation localized most of the activity in the endoplasmic reticulum. GEH activities with tributyrin and *p*-nitrophenylacetate as substrates were highest in the duodenum and jejunum; with palmityl-CoA (athcolester) as substrate, specific activity was highest in the ileum. A sharp decrease occurred in the ratio of GEH activity to thioester hydrolase (TEH) activity from the duodenum to the ileum (1,500 to 100). The presence of two distinct enzymes, GEH and TEH, was suggested by the different localization of these activities in the intestine, as well as by differential solubilization characteristics and by separation on a diethylaminoethyl-cellulose column. Gel electrophoresis showed that GEH and *p*-nitrophenylacetate hydrolase activities are coincident with hydrolytic activities against short and medium chain mono-, di-, and triglycerides. Mucosal GEH in neonatal rats was found to increase from about 1,000 mU/mg to 5,000 mU/mg over a 3-4 week period after weaning. The possible role of GEH in lipid degradation is discussed.

6818 THE RELATIVE FREQUENCIES AND DISTRIBUTION OF IMMUNOGLOBULIN-BEARING CELLS IN THE INTESTINAL MUCOSA OF NEONATAL AND WEANED PIGS AND THEIR SIGNIFICANCE IN THE DEVELOPMENT OF SECRETORY IMMUNITY.

(Eng.) Allen, W. D.; Porter, P. (Unilever Res. Lab., Colworth House, Sharnbrook, Bedfordshire, England). *Immunology* 32(5):819-824; 1977.

The proportions of cells containing IgM, IgA, or IgG and their distribution in the intestinal mucosa were studied in pigs ranging in age from 2 days to 12 weeks. Tissue blocks from the duodenum, jejunum, ileum, and spiral colon were stained for Ig's with fluorescein isothiocyanate and rhodamine isothiocyanate. All cell counts were expressed as the number or mean number of stained cells visible in 20 fields using x40 objective. Cells containing IgM (total, 1-9) were detected in the duodenal mucosa as early as 2 days of age. The duodenum was the main site of Ig proliferation, and even after 2 weeks, it contained 10 times the number of Ig-bearing cells than the other parts of the intestine. IgA cells (1-10) appeared in the duodenum at 4-5 days of age, and IgG cells (54-73) were found at 9 days. The Ig concentration was consistently higher in the duodenum than in the other sites. IgM cells appearing in the lamina propria suggest a local synthesis by immunocytes rather than derivation from serum. Weaning influenced the relative frequencies of IgM and IgA. In the duodenum, the lamina propria of 4-week-old suckling pigs contained a mean of 1,542 IgM cells and 1,039 IgA cells. However, IgA cells outnumbered IgM cells (1,433 to 1,117) in 4-week-old pigs that had been weaned for 1 week. At 12 weeks of age, nearly 90% of the cells in the weaned pigs contained IgA. These results and those of similar studies suggest that IgM is an important factor in the early development of the secretory immune response.

6819 PLASMA SECRETIN CONCENTRATION IN MAN: EFFECT OF INTRADUODENAL GLUCOSE, FAT, AMINO ACIDS, ETHANOL, HCl, OR INGESTION OF A MEAL.

(Eng.) Fahrenkrug, J.; Schaffalitzky De Muckadell, O. B. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Eur. J. Clin. Invest.* 7(3):201-203; 1977.

The effect of the intraduodenal infusion of isotonic saline, isotonic and hypertonic glucose, fat emulsion, amino acids, ethanol, and hydrochloric acid on the plasma concentration of immunoreactive secretin was studied in seven normal subjects. Only HCl (0.1 M) showed any effect. After acidification of the duodenum with HCl, a significant rise in plasma secretin concentration was observed from 1.3 ± 0.4 pM to a peak value of 13.0 ± 1.2 pM after 5 min. The concentration returned to the basal level within 15 min. In eight other normal subjects, the plasma secretin concentration was measured after the ingestion of a protein-rich meal. No significant changes were observed during the 2-hr postprandial period.

6820 VASOACTIVE INTESTINAL PEPTIDE (VIP): VARIATION OF THE JEJUNO-ILEAL CONTENT IN THE DEVELOPING RAT AS MEASURED BY RADIORECEPTORASSAY.

(Eng.) Laburthe, M.; Bataille, D.; Rosselin, G. (U-55, INSERM, 75571 Paris Cedex 12, France). *Acta Endocrinol. (Kbh.)* 84(3):588-599; 1977.

Variations in the amount of vasoactive intestinal peptide (VIP) in the rat jejunoileum (JI) with age were studied by measuring the binding of VIP to rat liver plasma membranes. The VIP were extracted from the JI of Wistar rats by 0.5 M acetic acid and then purified partially by adsorption on silicate. VIP content was measured by a radioreceptor assay in whic rat VIP competitively inhibited the binding of ^{125}I-labeled porcine VIP (pVIP) to rat liver plasma membranes at 30 C. Binding of ^{125}I-pVIP was inhibited 90% by 1 μg/ml rat VIP; the assay was sensitive to 0.5 ng/ml rat VIP. Synthetic derivatives of VIP and the structurally related hormone, glucagon, had no binding ability, and secretin had about 1% of the binding activity of native VIP. Native VIP content increased 340-fold from day 21 postcoitum (41 ± 4 ng/JI) to day 63 postpartum (14,110 ± 954 ng/JI). On a gut weight basis, VIP content increased slightly from day 2 postpartum (560 ± 36 ng/g gut) to day 14 (906 ± 109 ng/g) and then rose sharply until day 63 (2,672 ± 207 ng/g). Thus, the greatest increase in

VIP content began on day 14, coincident with an increase in gut weight and development. Both VIP content and gut weight reached a plateau level after 2 months. During this time, VIP content per milligram of JI protein also increased (10- to 12-fold). VIP content may be related to intestinal development or regulation of the digestive process.

GENERAL

6828 PERTECHNETATE DISTRIBUTION IN MAN AFTER INTRAVENOUS INFUSION: A COMPARTMENTAL MODEL. (Eng.) Hays, M. T.; Berman, M. (Veterans Admin. Central Office [151], 810 Vermont Ave., N.W., Washington, DC 20420). *J. Nucl. Med.* 18(9):898-904; 1977.

Using a primed infusion technique, the distribution of pertechnetate was monitored in normal volunteers over an 8-hr period. Two groups of subjects were studied, during hours 0-4 (n=8) and hours 4-8 (n=7), resp., of the infusion. At 6.5 hr, a large dose of NaI (1,000 mg) was administered i.v. to the second group. Plasma, salivary, and urinary radioactivities were assayed, and external counts were made of radioactivities over the neck, thigh, and right upper abdomen. A kinetic model was developed for pertechnetate based upon the distribution data, the iodide perturbation, and known physiology for pertechnetate and iodide. The model has three major subsystems: (1) the thyroid trap, (2) a whole-body distribution, containing plasma and two extravascular compartments, and (3) the gastrointestinal tract, including the salivary, stomach (including upper small intestine), and two lower intestinal compartments. One of the latter, which turns over very slowly, is believed to represent bowel wall. The large NaI dose markedly reduced transport into the compartments of the thyroid trap, the saliva, and the stomach and small intestine. This study shows that pertechnetate is distributed qualitatively but not quantitatively like iodide; unlike iodide, large bowel distribution plays an important role with this substance, especially in long-term studies.

6829 IN VIVO AND IN VITRO ASSESSMENT OF BARIUM SULPHATE SUSPENSIONS. (Eng.) Roberts, G. M.; Roberts, E. E.; Davies, R. L.; Evans, K. T. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff, England). *Br. J. Radiol.* 50(596):541-545; 1977.

A comparison was made between *in vitro* and *in vivo* tests in the canine stomach and small intestine using several brands of barium sulfate. There was considerable variation in the behavior of these suspensions between the *in vitro* and *in vivo* tests, particularly in the stomach. The results suggest that *in vitro* tests of this sort are of little value for assessing the relative advantages and disadvantages of these suspensions in demonstrating mucosal detail.

6830 RADIOIMMUNOASSAY OF THE ANTIDIARRHOEAL LOPERAMIDE.

(Eng.) Michiels, M.; Hendriks, R.; Heykants, J. (Janssen Pharmaceutica, Research Laboratoria, B-2340 Beerse, Belgium). *Life Sci.* 21(3):451-459; 1977.

Using antiserum produced in rabbits against loperamide, a sensitive and specific radioimmunoassay procedure for this antidiarrheal was developed. The drug was assayed directly in plasma from three healthy subjects in amounts as low as 50 pg. None of the known *N*-dealkylated metabolites of loperamide interfered with the radioimmunologic determination of loperamide in biological fluids. Four hours after the administration of a single p.o. dose of loperamide (4 mg), peak plasma levels, corresponding to about 0.75 ng/ml, were reached, and drug plasma concentrations could be measured up to 24 hr after administration. It is concluded that the method described is very specific for the determination of loperamide in man.

6831 METABOLIC EFFECTS OF PROLONGED ETHANOL ADMINISTRATION IN RATS TREATED WITH CLOFIBRATE.

(Eng.) Hillbom, M. E.; Poso, A. R.; Eriksson, C. J. P.; Franssila, K.; Hakkinen, H. M. (Res. Lab. State Alcohol Monopoly [Alko], Box 350, SF-00101 Helsinki 10, Finland). *Acta Pharmacol. Toxicol. (Kbh.)* 39(3):365-373; 1976.

A study was carried out on the effect of prolonged exposure to ethanol (by stomach tube, 6 g/kg body weight per day for 2 weeks followed by 9 g/kg for 1 week) on rats also receiving the antilipemic agent ethyl-α-*p*-chlorophenoxyisobutyrate (clofibrate, 0.2 g/kg body weight/day, s.c., beginning 9 days before and also accompanying ethanol adminstration). A control group received an equal volume of saline solution in place of clofibrate. After the first dose of ethanol, blood glucose levels in controls increased from 7.2 ± 0.7 mM to 8.7 ± 0.6 mM ($p<0.001$) whereas, in the clofibrate-treated group, there was an insignificant increase in blood glucose (from 7.1 ± 0.4 to 7.6 ± 0.6 mM). The blood ethanol concentrations were high in both the control and clofibrate-treated groups, 21 ± 12 and 19 ± 8 mM, resp. Eight hours after the final dose of ethanol, blood glucose levels in the control and clofibrate-treated groups were not significantly different (6.1 ± 0.7 and 6.4 ± 1.0 mM, resp.). The absence of an initial hyperglycemic response in the clofibrate-treated group resulted in decreased liver glycogen in these animals. The mean blood ethanol level in the clofibrate-treated group after prolonged ethanol exposure (16 ± 10.5 mM) was significantly lower than that in the control group (39.6 ± 11.3 mM, $p<0.005$). The rate of ethanol elimination in controls was approximately 70% of that in the experimental group. The mean liver-to-body ratio (g/100 g) in the clofibrate-treated animals (4.72 ± 0.27) was significantly lower than that in the controls (3.79 ± 0.31, $p<0.005$) 16 hr after the final dose. Rats eliminated ethanol more rapidly in the presence of clofibrate. There were no signs of ketoacidosis, hypoglycemia, or histological indications of inflammation of the liver in the clofibrate-treated group, indicating that ethanol was no more toxic to this group than to the controls. The controls showed a slight but insignificant increase in liver lipid content. The possibility that the adverse effects of alcohol in man may be prevented or alleviated by clofibrate treatment is discussed.

6832 THE SIGNIFICANCE OF SYMPATHETIC NERVOUS ACTIVITY FOR THE DEVELOPMENT OF THE INTESTINAL MUCOSAL LESIONS IN SHOCK.

(Eng.) Haglund, U.; Lundgren, O. (Dept. Physiology, Univ. Goteborg, Goteborg, Sweden). *Acta Chir. Scand.* 143(3):139-143; 1977.

The importance of sympathetic nervous activity in the development of intestinal mucosal lesions in hypotensive shock was studied in the feline gut. The extent of mucosal damage produced by lowering intestinal inflow pressure to 30-35 mm Hg for 2 hr was compared in acutely denervated intestines and in intestines in which the regional sympathetic vasoconstrictor fibers were electrically stimulated. Regional hypotension was produced by partial occlusion of the superior mesenteric artery. In one series of animals, the sympathetic fibers in the splanchnic nerves were stimulated bilaterally at 6 Hz throughout the hypotension. Mucosal damage was observed in both series. No statistically significant difference was demonstrated between the two series of experiments with regard to mucosal damage or blood pressure fall. It is concluded that sympathetic nervous activity does not contribute to any measurable extent to the development of mucosal damage and cardiovascular deterioration observed in connection with regional intestinal hypotension.

6833 PROTECTION OF MOUSE INTESTINE AGAINST GAMMA IRRADIATION BY 2-MERCAPTOPROPIONYLGLYCINE (MPG).

(Eng.) Devi, P. U. (Radiation Biology Lab., Univ. Rajasthan, Jaipur-302004, India). *J. Radiat. Res.* 18(2):160-163; 1977

In a preliminary attempt to investigate the protective action of 2-mercaptopropionylglycine (MPG) on the tissues of mammals exposed to high doses of ionizing radiation, adult Swiss albino mice were subjected to 1,200 r of gamma rays from a ^{60}Co MPG (20 mg/kg). The histopathological changes in th small intestinal villi were studied at postirradiation intervals of 2, 5, 14, and 28 days and were compared with observations from mice irradiated in the absence of MPG. Severe damage was observed in the villi of the animals receiving no protective drug, whereas, in the MPG-injected group, the villi were protected to some extent. An early recovery was effected in the MPG group, with the result that the normal structure was restored by the last interval studied.

6834 THE ROLE OF HISTAMINE RECEPTORS IN THE PATHOPHYSIOLOGY OF GASTRIC MUCOSAL DAMAGE.

(Eng.) Ress, W. D. W.; Rhodes, J.; Wheeler, M. H.; Meek, E. M.; Newcombe, R. G. (Univ. Hosp. Wales, Cardiff, Wales). *Gastroenterology* 72(1):67-71; 1977.

The effects of the H_1 and H_2 histamine receptor antagonists, mepyramine maleate and metiamide, resp., on the sensitivity of the gastric mucosal barrier to sodium taurocholate was studied to investigate the role of histamine in the pathophysiology of bile-induced damage to the mucosa. Two months prior to the experiments, gastric Heidenhain pouches were prepared in four mongrel dogs. In each experiment a solution was instilled into the pouch and changes in the volume and flux of H^+ and Na^+ were monitored during five 30-min periods. A standard acid solution (100 mM HCl, pH 1.2) was used during periods I, II, IV, and V, and a sodium taurocholate solution with an equimolar H^+ concentration was used in period III. Four sets of experiments were conducted: (1) constant infusion of metiamide (200 μg/50 ml/hr, i.v.), (2) injection of mepyramine (10 mg/kg, i.m.), (3) a combination of (1) and (2), and (4) constant infusion of normal saline (50 ml/hr, i.v.). The results of the control experiments and of those in which either mepyramine maleate or metiamide were given did not differ significantly. During periods I and II, there was a small loss of fluid from the pouch (overall mean, -0.2 ml). During period III (bile in the pouch), the volume recovered was consistently increased (overall mean, +0.7 ml); the absolute increase relative to period II was +0.9 ml ($p<0.001$). In period IV, there was a small overall gain of +0.2 ml, but there was a reversion to prebile values in period V. A decrease in the H^+ concentration and an increase in the Na^+ concentration occurred in each period, with the largest changes occurring during periods III and IV ($p<0.001$ and $p<0.005$ for H^+ and Na^+, resp.). Hence the overall H^+ flux was negative ($p<0.025$) and the overall Na^+ flux was positive ($p<0.005$) when compared to controls. In the experiment in which mepyramine maleate and metiamide were given together, there was no significant change in gastric fluid volume; the change in H^+ concentration in period III, although significantly greater than in period II ($p<0.03$), was much smaller ($p<0.001$) than in the first three types of experiments. The H^+ and Na^+ fluxes in periods III, IV, and V were not significantly different from those of periods I and II. The results indicate that changes in the ionic permeability of the gastric mucosal barrier are mediated through both H_1 and H_2 sites.

6835 STRESS DURATION, GASTRIC EMPTYING, AND ULCER DEVELOPMENT IN THREE STRAINS OF RATS.

(Eng.) Glavin, G. B.; Mikhail, A. A. (Dept. Psychology, Brock Univ., St. Catharines, Ontario, Canada). *Biochem. Med.* 18(1):58-63; 1977.

The effects of restraint, shock, and starvation on gastric emptying and ulcer development in Sprague-Dawley, Wistar, and Long-Evans rats were examined. In general, rumenal pathology increased over time, while glandular ulcers decreased. Sprague-Dawley rats were the most ulcer-susceptible strain ($p<0.0001$) in comparison with the other two strains, particularly in response to restraint stress ($p<0.0003$). Forty-eight hours of prestress food deprivation was found to ensure an empty stomach at autopsy. The pattern of interactions between strains and treatments suggested that differences in ulcer susceptibility were a treatment-specific phenomenon, and should be considered when designing experimental ulcer studies.

6836 EFFECT OF DIFFERENT FACTORS MODIFYING THE ACTIVITY OF SOME ENZYME SYSTEMS OF THE ENDOPLASMIC RETICULUM ON THE SENSITIVITY OF CELL ORGANELLES AGAINST THE DAMAGING ACTION OF CHEMICAL AGENTS. I: INTERRELATIONS BETWEEN THE ACTIVITY OF SOME ENZYME SYSTEMS LOCATED IN ENDOPLASMIC RETICULUM AND HEPATOTOXICITY OF CARBON TETRACHLORIDE.

(Eng.) Popov, Ch. S.; Yantchev, I.; Georgiev, G.; Geneva, L. (Higher Inst. Zootechnics and Veterinary Medicine, 6000 Stara Zagora, Bulgaria). *Br. J. Exp. Pathol.* 57(5):593-603; 1976.

The stability and activity of the hepatic lysosomal and microsomal enzyme systems of Wistar rats were studied to determine the protective effects of stress against the hepatotoxicity of carbon tetrachloride (CCl_4) and its free-radical metabolites. The animals were divided into several groups and subjected to various stresses: tumor growth (Guerin ascites tumor or Pliss lymphosarcoma), sleep deprivation (40 hr), partial immersion in 70 C water for 10 sec 24 hr prior to sacrifice (burning), dehydration (4 days), two 30-min exposures to temperatures of 38-41 C (overheating), or injections 3 hr prior to sacrifice of lanthanum (40 mg/100 g) or ruthenium red (2.5 mg/100 g, i.p.). Rats from each group were then given CCl_4 (0.2 ml/100 g) by stomach tube 6 hr before sacrifice. A delay in the increase of "free" acid phosphatase and a reduction in the increase of "free" acid phosphatase and malate dehydrogenase released from the large-granule fractions by CCl_4 indicated a stabilizing effect of tumor growth, burning, and dehydration on liver lysosomes and mitochondria. Burning also prevented some of the ultrastructural changes produced by CCl_4. Sleep deprivation and the lymphosarcoma clearly inhibited the activity of the microsomal peroxidase system, which is thought to be at least partially responsible for the transformation of CCl_4 into a free-radical form. Dehydration, burning, overheating, and the ascites tumor had variable effects on this system. Burning and overheating inhibited the aniline hydroxylase system, but the other stresses activated it. There was a frequent lack of correlation between strong antagonism to CCl_4 and a strong inhibitory effect on the microsomal peroxidase system. However, based on other studies, it is suggested that many antagonists of CCl_4 act by inhibiting its transformation into a free-radical form.

6837 NEW ASPECTS OF GASTROINTESTINAL HORMONES. (Ger.) Domschke, W.; Domschke, S. (Med. Univ.-Klinik, Krankenhausstrasse 12, 852 Erlangen, W. Germany). *Fortschr. Med.* 95(14):967-971; 1977.

6838 SPECIFIC DYNAMIC EFFECT OF FOOD ON THE INTESTINAL HORMONAL SYSTEM. (Rus.) Ugolev, A. M. (I. P. Pavlov Inst. Physiology, USSR Acad. Sciences, Leningrad, USSR). *Ter. Arkh.* 48(5):66-73; 1976.

DIAGNOSTIC PROCEDURES

6850 A NEW ENZYMATIC METHOD FOR DETERMINATION OF SERUM CHOLINE-CONTAINING PHOSPHOLIPIDS. (Eng.) Takayama, M.; Itoh, S.; Nagasaki, T.; Tanimizu, I. (Res. Lab., Nippon Schoji Kaisha, Ltd., 24-3, Sho 2-chome, Ibaraki-city, Osaka, Japan). *Clin. Chim. Acta* 79(1):93-98; 1977.

A new enzymatic method was developed for the determination of serum choline-containing phospholipids with a combined enzymatic method using phospholipase D (from *Streptomyces* species), choline oxidase (from *Arthrobacter* species), and peroxidase. The method is reproducible, and the results correlate well with those obtained by a conventional digestive method. The method affords better specificity, requires a smaller quantity of the sample and shorter time than those previously reported, and has excellent precision.

6851 AN IN VITRO INVESTIGATION OF BARIUM MEALS. (Eng.) Simmonds, R. J.; James, A. M. (Dept. Chemistry, Bedford Coll., Univ. London, Regent's Park, London NW1 4NS, England). *Cytobios* 15(60):191-200; 1976.

A technique is described for the *in vitro* study of the interaction of various barium sulfate suspensions, used as radiopaques, with a rat ileum. The technique allows close approximation to the *in vivo* situation if there is accurate control of certain experimental conditions: (a) the animal must be fasted for 24 hr before the experiment, (b) tissue slices must be removed from the same region of the intestine (5-20 cm from stomach), (c) the mucosal surface of the ileum must not be disturbed during cutting or washing, (d) during exposure to the radiopaque the glass cells must be gently agitated, (e) freezing must be instantaneous, and (f) tangential sections must not be taken from the extreme edges of the frozen tissue. The thickness of the radiopaque retained at the gut surface was directly related to the particle concentration of the suspension (50%, 25%, and 12.5% w/v), while the uniformity of the layer showed the reverse trend. There was no significant difference in either the thickness or the uniformity of the adhering layer over the pH range 3-8. Less stable suspensions produced thicker but not uniform adhering layers of the radiopaque, and less viscous suspensions gave better coating of the gut surface. The nature of the stabilizing agent or the surface charge carried by the particles did not affect the adhesion of the particles to the ileal mucus. The technique is convenient, quick, economical, and reproducible, and its usefulness in comparing the properties of various radiopaques could be greatly improved if a better method of assessing the adhering layer of radiopaque were available.

6852 GALLIUM-67 DEPOSITION IN THE HUMAN GASTRO-INTESTINAL TRACT. (Eng.) Newstead, G.; Taylor, D. M.; McCready, V. R.; Bettelheim, R. (Royal Marsden Hosp., Sutton, Surrey, England). *Int. J. Nucl. Med. Biol.* 4(2):109-112; 1977.

The relative distribution of ^{67}Ga between the intestinal walls and contents was studied. Concentrations of ^{67}Ga in the normal human gastrointestinal tract were measured in samples obtained at operation 5-72 hr after the administration of 300-500 μCi of ^{67}Ga citrate. The concentrations in stomach, ileum, colon, and rectum were about 2.5-15% dose/kg wet tissue, and no clear evidence of a change in concentration with time after injection was seen. These values are comparable with those previously observed in liver and spleen. Studies in 25 samples of colorectal tumors showed a mean tumor:normal tissue concentration ratio of 3.7:1. A comparison of ^{67}Ga and DNA concentrations in small pieces of tumor and normal tissue suggested a good correlation between ^{67}Ga uptake and the cellularity of the tissue for normal tissues but not for tumors. Samples of gallbladder bile obtained from four patients at operation at 5, 24, and 48 hr after ^{67}Ga administration contained about 2% dose/l, and gel filtration studies showed that the nuclide was present as a low molecular weight complex. Assuming a bile flow of about one liter per day, this would correspond to a biliary excretion of between 2% and 3% per day, which, if there is no reabsorption of ^{67}Ga is sufficient to account for reported values for the fecal excretion of ^{67}Ga. These results suggest that the concentrations of ^{67}Ga occurring in the intestinal walls are probably higher than those in the intestinal contents. It seems worthwhile to reassess the value of ^{67}Ga citrate as an agent for the localization of intestinal tumors after the colon and rectum have been emptied by a suitable regimen.

6853 RETROSPECTIVE COMPARISON OF RADIONUCLIDE SCANS AND COMPUTED TOMOGRAPHY OF THE LIVER AND PANCREAS. (Eng.) MacCarty, R. L.; Wahner, H. W.; Stephens, D. H.; Sheedy, P. F.; Hattery, R. R. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Am. J. Roentgenol.* 129(1):23-28; 1977.

Computed tomography (CT) and radionuclide examinations of the liver and pancreas were compared retrospectively in 50 patients to evaluate their value as diagnostic tests. CT was superior to ^{75}Se-selenomethionine in evaluating pancreatic disease. Both ^{99m}Tc-sulfur colloid scans and CT scans were sensitive indicators of liver masses; however, there were more false-positive ^{99m}Tc-sulfur colloid scans (16%) than false-positive CT scans (4%). CT was superior in detecting biliary obstruction and ascites, in assessing diseases that involved the liver extrinsically, and in evaluating the status of adjacent organs. ^{99m}Tc-sulfur colloid scans were more sensitive in detecting diffuse non-neoplastic liver diseases (cirrhosis, hepatitis, and cholangitis). Simultaneous interpretation of CT and radionuclide scans was often more helpful than independent interpretation, and the two techniques are therefore complementary.

6854 DEFINITIVE ROLE OF CT SCANNING OF THE PANCREAS. (Eng.) Haaga, J. R.; Alfidi,

R. J.; Havrilla, T. R.; Tubbs, R.; Gonzales, L.; Meaney, T. F.; *et al.* (Cleveland Clinic, 9500 Euclid Ave., Cleveland, OH 44106). *Radiology* 124 (3):723-730; 1977.

The diagnostic accuracy of angiography, ultrasonography, and computed tomography (CT) for detecting neoplasia and inflammation of the pancreas was compared. In a group of 188 patients, 192 Ct scans of the pancreas were done. The patients were divided into two groups: those with surgical confirmation and those with clinical correlation. CT was the most effective method of detecting neoplastic (28/32 surgically confirmed and 94/106 clinically confirmed cases) and inflammatory disease (13/19 surgically confirmed and 8/9 clinically confirmed acute pancreatitis cases). Ultrasound correctly diagnosed 4 of the 7 neoplasms, and angiography was correct concerning 7 of 12 neoplasms in the surgically confirmed group of cases. The overall accuracy for both groups (surgical and clinical) of CT was 83% and of ultrasound was 68%. CT was the most accurate means of detecting the primary disease. Inflammatory disease of the pancreas was amenable to CT evaluation if there were morphologic changes such as enlargement or if any alteration in the attenuation numbers was produced by deposition of calcium or collections of fluid. The full extent of the disease process, including involvement of the retroperitoneum and metastasis to the liver, was visualized by CT in one examination only. All three methods for the evaluation of the pancreas have definite diagnostic roles.

6855 COMPUTED TOMOGRAPHIC EVALUATION OF THE PANCREAS. (Eng.) Stanley, R. J.; Sagel, S. S.; Levitt, R. G. (Washington Univ. Sch. Medicine, 510 South Kingshighway, St. Louis, MO 63110). *Radiology* 124(3):715-722; 1977.

A large number of patients (352) were studied in attempts to clarify the diagnostic role of computed body tomography (CT). A CT diagnosis of normal pancreas was made in 218 cases. The majority of cases (10 of the 14 patients) that could not be confirmed as normal correlated with a subsequent benign clinical course. The size, shape, and position of the normal pancreas was highly variable. Specific abnormality, diagnosed by CT in 88 cases, was categorized as either cancer (50 patients), acute or chronic pancreatitis (27 patients), pseudocysts (9 patients), or miscellaneous (2 patients, lymphoma posterior to the body and tail of pancreas). Another 20 patients were considered "indeterminate" and had surgery even though no other sign of malignancy was present apart from smooth focal enlargement of pancreas. Although there was no operative or histologic confirmation in 18 of 27 cases diagnosed as acute or chronic pancreatitis, the history, serum chemistry studies, and clinical course were consistent in all but 3 patients (in whom adequate follow-up was lacking). CT and ultrasound examinations were compared in 45 patients, and the interpretations were in agreement. However, when the results of the two techniques varied, CT was correct 81% of the time in the confirmed cases. CT and ultrasound techniques are complementary to each other. CT is useful in following the clinical course of patients to determine their response to radiation therapy, chemotherapy, or surgical intervention.

6856 COMPUTED TOMOGRAPHY OF THE NORMAL PANCREAS. (Eng.) Kreel, L.; Haertel, M.; Katz, D. (Div. Radiology, Clinical Res. Center, Harrow, Middlesex HA1 3UJ, England). *J. Computer Assisted Tomography* 1(3):290-299; 1977.

The normal anatomy of the pancreas was demonstrated by computed tomography (CT) with the EMI general purpose scanner in 50 patients without pancreatic disease and in 15 normal postmortem pancreas. The problems of optimal demonstration of the pancreas in CT and the possible causes of misinterpretation of the pancreatic axial tomography are considered. The ventrodorsal diameter of the normal pancreas was found to be 23 ± 3.0 mm for the head, 19 ± 2.5 mm for the neck, 20 ± 3.0 mm for the body, and 15 ± 2.5 mm for the tail. In assessing these values, it is important to be sure that adjacent structures such as the portal vein, splenic vein, and duodenum are not included in the measurement; that the measurements are taken on scans of maximum resolution without movements; and that the measurements are strictly related to the arteroposterior or ventrodorsal diameter. A close correlation between the ventrodorsal diameter and craniocaudal diameter of approximately 1:2 is reported. In the majority of patients, the pancreas appeared to have smooth contours, but in 20% of the patients, it appeared as a lobulated organ. It is reported that gantry tilt will distort the diameter measured. Careful preparation of the patient with a low residue diet, injection of anticholinergic drugs, breath-holding during the exposure time, and avoidance of dense gastrointestinal contrast medium during the period of CT examination are suggested.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6862 ADENOCARCINOMA IN THE COLUMNAR-LINED (BARRETT) ESOPHAGUS: CASE REPORT AND REVIEW OF THE LITERATURE. (Eng.) Poleynard, G. D.; Marty, A. T.; Birnbaum, W. B.; Nelson, E. R.; Reilly, R. R. (Naval Regional Medical Center, 7500 E. Carson St., Long Beach, CA 90882). *Arch. Surg.* 112(8):997-1000; 1977.

Three patients with adenocarcinoma arising in the columnar-lined lower esophagus are described. The patients were three men, aged 47, 54, and 25 yr, the latter being the youngest man reported with adenocarcinoma in Barret's esophagus. Barium swallow revealed a stricture in all cases, and the diagnoses were confirmed by endoscopic biopsy. Hiatal hernia was present in two patients. All patients survived esophagogastrectomy and radiotherapy, but each had metastatic disease and a guarded prognosis. A review of the literature revealed a male/female ratio of 3:1 for this disorder, with a mean age for men and women of 53 and 61 yr, resp. Columnar-lined lower esophagus is seen in up to 11% of patients with reflux esophagitis; adenocarcinoma later develops in 2.4-8.5%. Patients with documented hiatus hernia and/or significant reflux symptoms or both should undergo esophagoscopy. If columnar-lined esophagus is found, an antireflux procedure should be performed. All patients with columnar-lined esophagus should be closely followed up. In cases of adenocarcinoma in which curative resection is contemplated, complete extirpation of all columnar-lined lower esophagus is desirable.

6863 GASTRO-OESOPHAGEAL ACID REFLUX IN PATIENTS WITH SYMPTOMATIC HIATUS HERNIA AND EFFECT OF A MODIFIED BELSEY MK IV REPAIR ON ACID REFLUX. (Eng.) Boesby, S. (Odense Sygehus, Sdr. Boulevard 29, DK-5000 Odense, Denmark). *Scand. J. Gastroenterol.* 12(5):553-569; 1977.

Twelve-hour continuous recording of pH at the distal end of the esophagus was carried out in 59 patients with sliding hiatal hernia and symptoms suggestive of gastroesophageal reflux, and the results were compared with those obtained in normal subjects. The patients were grouped into those with heartburn (group A) and those with heartburn and pain (group B). The mean duration of pH ≤ 2.3, pH ≤ 3, pH ≤ 4, and pH ≤ 5, expressed in percentages of the total time of recording was longer in patients than in normal subjects. There was no difference in mean number of reflux episodes between patients and normal subjects. The clearest separation between the two groups was obtained by the variable duration of pH ≤ 5 (group A compared to normal subjects, $p < 0.0002$; group B compared to normal subjects, $p < 0.00006$). Irrespective of the variable used, the results did not seem to be related to the degree of severity of the symptoms. Individual sensitivity of the esophageal mucosa, the content of bilious components in the refluxed material, and the semiquantitative character of the investigation may, in part, account for the results. Furthermore, the same investigation was carried out before and three months after a modified Belsey MK IV repair in 39 patients with hiatal hernia and symptoms indicating surgical treatment. The operation was followed by a reduction in the tendency to acid reflux (pH ≤ 5, $p < 0.00006$), probably as a result of an increase in the competence of the gastroesophageal region.

6864 MALLORY-WEISS SYNDROME: A CHANGING CLINICAL PICTURE. (Eng.) Todd, G. J.; Zikria, B. A. (Presbyterian Hosp., Columbia-Presbyterian Medical Center, New York, NY). *Ann. Surg.* 186(2):146-148; 1977.

The records of 16 patients with upper gastrointestinal hemorrhage secondary to endoscopically or surgically documented Mallory-Weiss syndrome were reviewed. The patients ranged in age from 26-68 yr (9 men), and a history of chronic heavy alcohol consumption was present in 14 patients. In 13 of 18 bleeding episodes, retching and regurgitation of food or clear material occurred prior to the onset of hematemesis. Painless hematemesis was reported in 17 of the 18 episodes. The diagnosis was made endoscopically in 16 of 17 instances. Surgery was performed in six bleeding episodes. Among the surgically treated cases, there was one death from hepatic failure 16 days after oversewing both a gastric mucosal tear and a bleeding varix in a 62-yr-old man with cirrhosis. A review of the literature reveals that the clinical spectrum, prognosis, and opinion regarding the etiology and treatment of the syndrome have changed in the last decade. Increased awareness of gastroesophageal lacerations secondary to emesis, as well as other causes of significantly increased intraesophagogastric pressures, and widespread use of fiberoptic endoscopy have resulted in the identification of this syndrome with increasing frequency. It is recommended that endoscopy be carried out in all cases of upper gastrointestinal hemorrhage, and that patients with Mallory-Weiss syndrome be managed medically unless hemorrhage is massive or persistent.

STOMACH

5874 ANGIOGRAPHIC MANAGEMENT OF GASTROINTESTINAL BLEEDING WITH VASOPRESSIN. (Eng.) Kadir, .; Athanasoulis, Ch. A. (Massachusetts General osp., Boston, MA 02114). *Fortschr. Roentgenstr.* 27(2):111-119; 1977.

elective arteriography and infusions of vasopressin 0.2-0.4 U/min for 20-30 min) have become valuable ools for localization and therapy of acute gastro-ntestinal hemorrhage. These procedures are best pplicable to those patients in whom conservative easures are unsuccessful and in those who are poor urgical risks. Gastric mucosal hemorrhage can be reated successfully in about 84% of the cases. astric ulcer can be treated successfully in about 5-70% of cases. Acute colorectal bleeding is con-rolled in about 90% of patients. Caution is sug-ested in the use of vasopressin under anesthesia or imultaneously with ganglionic blocking agents or in atients with ischemic heart disease. Careful fluid nd electrolyte monitoring and occasional use of di-retics is suggested to avoid retention of water and lectrolyte imbalance.

375 ELECTRON MICROSCOPIC STUDY OF SIGNET-RING CELLS IN DIFFUSE CARCINOMA OF THE HUMAN TOMACH. (Eng.) Yamashiro, K.; Suzuki, H.; Nagayo, (Pathology Lab., Aichi Cancer Center, Res. Inst., ikusa-ku, Nagoya 464, Japan). *Virchows Arch. athol. Anat.*] 374(4):275-284; 1977.

The signet-ring cells seen in six cases of gastric carcinoma of the diffuse type were studied by light and electron microscopy to develop new methods for differentiating diffuse gastric carcinoma. These cells were classified into three main types (A, B, and C) based on intracellular mucous granules, nuclei and cellular organelles, and their reactions to PAS and Alcian-blue staining. Type A signet ring cells had round nuclei in the center, abundant cell organelles, sparsely distributed dense mucous granules (0.3-0.5 μ), and PAS-staining only. The type B cells had eccentric, elliptical nuclei, fewer cell organelles, moderate-density medium mucous granules (0.5-1 μ), and mainly PAS-staining. The type C cells had peripherally compressed nuclei, markedly decreased cell organelles, low-density large mucous granules (2 μ), and stained mainly with Alcian-blue. The gradual transition of type A cells to type B and the subsequent change of type B to type C suggest successive stages in maturation of these cells that arise from the same cell system. These cells, especially those of type B, resemble the mucous neck cells of the corpus and the glands of the pylorus. The appearance of type A signet-ring cells can be regarded as an initial malignant change in the nonmetaplastic gastric mucosa.

6876 AN IN VIVO STATHMOKINETIC STUDY OF CELL PROLIFERATION IN HUMAN GASTRIC CARCINOMA AND GASTRIC MUCOSA. (Eng.) Wright, N. A.; Britton, D. C.; Bone, G.; Appleton, D. R. (Radcliffe Infirmary, Oxford, England). *Cell Tissue Kinet.* 10(5):429-436; 1977.

Cell production rates (CPR) were studied in 11 patients with carcinoma of the stomach using an *in vivo* technique (determination of mitotic indices using 3 μm paraffin sections) with vincristine (0.045 mg/kg body weight), to find a kinetic parameter in individual human tumors that could be used to predict therapeutic responses to a specially designed radiotherapeutic and chemotherapeutic regimen. The adjacent normal mucosa and hyperplastic and metaplastic gastric mucosa were also studied. The CPR for normal mucosa varied from 8-16 cells/1,000 cells/hr, and for carcinomas it varied from 3 to 24 cells/1,000 cells/hr. The CPR appeared elevated in hyperplastic mucosa (22.5-30.5 cells/1,000 cells/hr) and in mucosa displaying intestinal metaplasia (21.5-33.0 cells/1,000 cells/hr). Because of the very large variation in the data, comparison between individual tumors and normal mucosa is not regarded as worthwhile at the present stage of development of this procedure.

6877 TREATMENT OF GASTRIC CANCER, WITH SPECIAL REFERENCE TO THE SURVIVALS OF THE CANCER PATIENTS TREATED WITH MULTIPLE COMBINATION MFC THERAPY OR IMMUNOCHEMOTHERAPY OF MFC PLUS OK-432 (NSC B116209).

(Eng.) Suga, S.; Tsunekawa, H.; Washino, M.; Makino, N.; Tamura, Z.; Goto, S. (Natl. Nagoya Hosp., Naka-ku, Nagoya, 460 Japan). *Gastroenterol. Jpn.* 12(2):20-29; 1977.

Comparative study of the survival of 81 patients (35-80 yr old) with advanced gastric cancer is reported. Fifty-five patients were treated with a combination chemotherapy (MFC therapy) of mitomycin C (0.08 mg/kg), 5-fluorouracil (10 mg/kg), and cytosine arabinoside (0.8 mg/kg) administered i.v. twice a week for the first 2-3 weeks and then once a week until the patient's leukocyte count became less than 2,000-3,000/mm^3 or until the patient's platelet count dropped to less than 7-10 x $10^4/mm^3$. Twenty-six patients were treated with an immunochemotherapy of MFC plus OK-432 (i.m.) given in increasing doses (0.2-2.0 mg) four times per week for 2 weeks, 2.0 mg/kg doses three times a week for 6 weeks, and 2.0 mg/kg doses once a week thereafter. Fifty-percent survival times were 5.4 months for the MFC group, and 7.5 months for the MFC plus OK-432 group. One-year survival rates of each group were 13 and 35%, resp. The 2-yr survival was null for the MFC group, and 13% for the MFC plus OK-432 group. Thus, the patients treated with MFC plus OK-432 showed significantly longer survival compared to the patients treated with MFC alone ($p<0.05$). The case report of a 38-yr-old man with primary gastric cancer and skin metastasis is presented to illustrate a remarkable improvement of the stomach lesions and eventual complete remission on MFC plus OK-432 therapy. Two patients showed remarkable improvement initially on MFC plus OK-432 therapy, but, though still living, have developed recurrence of tumors. Because of the toxicity and/or the ineffectiveness of MFC during long-term administration, 5-fluorouracil *per os* plus OK-432 is recommended as a maintenance therapy for gastric cancer.

6878 CHRONIC EROSIVE (VERRUCOUS) GASTRITIS: A STUDY OF 108 PATIENTS.

(Eng.) Green, P. H. R.; Fevre, D. I.; Barrett, P. J.; Hunt, J. H.; Gillespie, P. E.; Nagy, G. S. (Royal North Shore Hosp. Sydney, St. Leonards N.S.W., 2065 Australia). *Endoscopy* 9(2):74-78; 1977.

One hundred and eight cases of chronic erosive gastritis diagnosed from 3,800 upper gastrointestinal endoscopies, during a 6-yr period, were reviewed. Gastritis occurred together with gastric ulceration in 11 patients, with duodenal ulceration in 23, with gastric malignancies in 4, and with esophagitis in 1. There was a significant ($p<0.01$) relation between the existence of duodenal ulcer together with chronic erosive gastritis. Chronic erosive gastritis occurred most frequently in men aged 60-69 yr. In 18 patients, gastritis was observed during emergency endoscopy for gastrointestinal bleeding; 11 had associated lesions that were thought to be responsible for the bleeding.

6879 PROGNOSIS OF MEDICALLY TREATED GASTRIC ULCER: A PROSPECTIVE ENDOSCOPIC STUDY.

(Eng.) Halse, S. A.; Kristensen, E. M.; Moller Jensen, O.; Morkbak, N. K. (Copenhagen County Hosp., S. Elisabeth, DK 2300 Copenhagen S, Denmark). *Scand. J. Gastroenterol.* 12(4):489-495; 1977.

Fifty-four patients with endoscopic evidence of gastric ulcer (greater than 1.5 cm in 6 patients and less than 1.5 cm in 48 patients) in the antrum (63%) and the body (37%) were studied. Patients with ulcer showing incipient healing, superficial erosions, manifest or suspected malignancy, or indication for surgery were excluded. The study was comprised of a treatment phase and a follow-up phase. The treatment phase covered the time from diagnostic gastroscopy until complete healing of the ulcer. During this period the patients were treated with antacids and anticholinergics and were advised to abstain from alcohol and smoking. If indicated by their clinical condition, the patients were admitted to hospital. During the treatment phase, endoscopy was performed at intervals of 3-6 weeks until healing. During the follow-up phase, endoscopy was carried out in the event of dyspeptic complaints that might indicate recurrent ulcer. The healing and recurrence rates for various periods were calculated by the aid of the life-table method. After 1 month of treatment, 13% of the patients exhibited healing, after 2 months 29%, after 3 months 41%, and after 12 months 79%. In 1 month, 9% of the primarily healed ulcers had recurred, in 2 months 15%, in 3 months 22%, and in 12 months 43%. The healing rate is appreciably lower than results previously reported in the literature, whereas the recurrence rate is in closer agreement with that found in previous studies.

6880 TREATMENT OF CHRONIC GASTRIC ULCER: A STUDY OF THE TREATMENT RECEIVED BY 135 GASTRIC ULCER PATIENTS IN A WESTERN COMMUNITY.

STOMACH

Peptic Ulcers

6911 HLA-B5 ASSOCIATED WITH DUODENAL ULCER. (Eng.) Rotter, J. I.; Rimoin, D. L.; Gursky, J. M.; Terasaki, P.; Sturdevant, R. A. L. (Harbor General Hosp., 100 W. Carson St., Torrance, CA 90509). *Gastroenterology* 73(3):438-440; 1977.

In search for further genetic factors contributing to ulcer diseases, the frequency of histocompatibility antigens (HLA) was studied in 77 men with duodenal ulcer. The patients were typed for the HLA-A and -B loci. Thirteen of 54 Caucasian men had the B5 antigen, compared to 10% of 3,895 controls; this was significant ($p<0.0016$) even when the p value was multiplied by the number of antigens tested (28). In 23

Negro patients, three antigens were increased in frequency: A10--30%, A11--9%, and Bw22--26%; the values in 330 controls were 12%, 1%, and 10%, resp. ($p<0.03$, $p<0.03$, and $p<0.05$, resp.), but were not significant when the p values were multiplied by the number of antigens tested. A significant association was demonstrated between duodenal ulcer and HLA-B5 in Caucasian men, with a relative risk of 2.9, greater than that associated with the combination of blood group O and nonsecretor status.

6912 AUGMENTED HISTAMINE TEST--DIAGNOSTIC AND PROGNOSTIC VALUES.

(Eng.) Sun, D. C. H.; Mirza, A. H.; Mitchell, C. S., Jr. (Good Samaritan Hosp., Box 2989, Phoenix, AZ 85062). *Am. J. Gastroenterol.* 67(4):338-344; 1977.

The diagnostic and prognostic values of the augmented histamine test were assessed in 107 controls, 48 patients with gastric ulcer, and 141 patients with duodenal ulcer. The mean basal acid secretion and maximal acid output (MAO) were significantly higher in duodenal ulcer patients than in normal subjects (0.344 versus 0.155 mEq). Ulcers of the body of the stomach were associated with lower than normal levels of secretion, whereas ulcers of the prepyloric region were associated with higher than normal levels. Among the patients with duodenal ulcer, 101 patients had an MAO above the upper limit of normal (20.4 mEq/hr). Conversely, a patient with an MAO of less than 12.4 mEq/hr was unlikely to have duodenal ulcer disease. The use of the ratio of MAO to actual body weight did not increase the diagnostic discrimination between normal subjects and those with duodenal ulcer. Duodenal ulcer patients with complications had a significantly higher MAO to histamine ratio than those without complication. The finding of an MAO greater than 40 mEq/hr is highly suggestive of the presence or the imminence of a complication.

6913 CLINICAL PICTURE OF PEPTIC ULCERATION DIAGNOSED ENDOSCOPICALLY.

(Eng.) Sheppard, M. C.; Holmes, G. K. T.; Cockel, R. (Selly Oak Hosp., Birmingham, England). *Gut* 18(7):524-530; 1977.

Clinical features and laboratory data are presented for 100 patients with benign gastric ulcers and 150 patients with duodenal ulcers confirmed endoscopically. Abdominal pain was the commonest indication for endoscopy (93% for gastric ulcer, 87% for duodenal ulcer) but examinations for acute gastrointestinal hemorrhage were performed in 32% of the gastric ulcer patients and 31% of the duodenal ulcer patients. There were no clinical features that clearly distinguished gastric from duodenal ulceration. However, younger gastric ulcer patients (<40 yr old) had only mid-lesser curve (50%) or distal stomach (50%) ulcers, whereas elderly gastric ulcer patients were more likely to have high lesser curve ulcers (66% of those 70-79 yr of age). Elderly patients presented more commonly with hemorrhage, with those >80 yr old showing 60% and 100% incidences of acute bleeding in cases of gastric and duodenal ulcer, resp. Younger patients tended to present with pain more often, with patients <40 yr of age showing 75% and 60% incidences of pain in gastric and duodenal ulcer, resp. All women presenting with hemorrhage were >50 yr old, while 6% of the men bleeding from gastric ulcer and 40% of the men bleeding from duodenal ulcer were under this age. When anemia (hemoglobin <13 g/dl in men and <12 g/dl in women) was present, it was almost always associated with a history of a recent acute gastrointestinal hemorrhage in both gastric and duodenal ulcer patients.

6914 HEALING OF DUODENAL ULCER WITH AN ANTACID REGIMEN.

(Eng.) Peterson, W. L.; Sturdevant, R. A. L.; Frankl, H. D.; Richardson, C. T.; Isenberg, J. I.; Elashoff, J. D.; *et al.* (Veterans Admin. Hosp., 4500 S. Lancaster Rd., Dallas, TX 75216). *N. Engl. J. Med.* 297(7):341-345; 1977.

To determine whether a large-dose antacid regimen is effective in promoting duodenal ulcer healing, 74 patients with endoscopically-proved duodenal ulcer completed a 28-day double-blind clinical trial in which the results of this regimen were compared with those of placebo. The ulcer healed completely in 28 of the 36 antacid-treated as compared with 17 of the 38 placebo-treated patients ($p<0.005$). The antacid regimen was not more effective than placebo in relieving ulcer symptoms. Presence or absence of symptoms during the fourth treatment week was a poor predictor of presence or absence of an ulcer crater. Ulcers of placebo-treated patients who smoked cigarettes were less likely to heal than those of nonsmokers ($p=0.03$). Except for mild diarrhea, no side-effects of the antacid regimen were observed. It is concluded that a large-dose antacid regimen hastens the healing of duodenal ulcer.

6915 EFFECTS OF CIMETIDINE AND POLDINE ON NOCTURNAL GASTRIC SECRETION.

(Eng.) Saunders, J. H. B.; Cargill, J. M.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee, Scotland). *Digestion* 15(5):452-456; 1977.

In view of the importance of persistent exposure of the duodenal bulb to acid and pepsin in the pathogenesis of duodenal ulceration, the effects of cimetidine and of a combination of cimetidine with poldine on 12-hr nocturnal gastric secretion were compared in six patients with duodenal ulcer. Cimetidine at 200 and 400 mg p.o. inhibited nocturnal secretion of acid to 29% and 34% of the control values, resp., but only slightly inhibited the nocturnal secretion of pepsin (to 60% and 90% of the control values at the two doses, resp.). The administration of cimetidine (200 or 400 mg) together with poldine (4 mg, p.o.) augmented the inhibition of the nocturnal secretion of acid (to 13% of control with 200 mg cimetidine amd to 23% of control with 400 mg) and of pepsin (to 25% and 57%, resp.). The combination of an H_2-receptor blocking drug with an anticholinergic drug will have therapeutical application in the management of duodenal ulceration.

6916 TRANSIENT NEUTROPENIA IN A PATIENT RECEIVING CIMETIDINE. (Eng.) Ufberg, M. H.; Brooks, C. M.; Bosanac, P. R.; Kintzel, J. E. (Allentown General Hosp., Allentown, PA 18102). *Gastroenterology* 73(3):635-638; 1977.

The case of a patient who developed transient neutropenia while receiving cimetidine is reported. The patient, a 62-yr-old man, was being treated with cimetidine for an intractable duodenal ulcer while on maintenance hemodialysis. The patient had received propranolol and hydralazine prior to cimetidine therapy, but these were discontinued 7 days prior to the start of cimetidine therapy. He received 300 mg of cimetidine p.o. every 12 hr; on the days of dialysis, he received an extra dose of 300 mg 2 hr before the procedure. An upper gastrointestinal series 17 days after the beginning of this regimen demonstrated complete ulcer healing. Liver function tests throughout the treatment period remained normal. The patient was anemic throughout treatment. On the 15th day of cimetidine therapy, a total WBC count of 3,000 cells/mm^3 was observed with 33% granulocytes, and the cimetidine was stopped on this day. On the second and third post-therapy days, the total counts were 1,800 and 1,300, resp., and there were only 2% neutrophils. A bone marrow aspiration 18 hr after cimetidine withdrawal indicated a moderate left shift in the myeloid series consistent with a drug-induced granulocytopenia with peripheral destruction of the granulocyte series. By the fourth day after the drug was discontinued, the granulocyte count was normalizing, and neutropenia did not recur. This case represents the first hematologic complication of cimetidine therapy. The probable mechanism was peripheral destruction of the granulocyte series.

6917 A PRAGMATIC TRIAL OF CIMETIDINE IN DUODENAL ULCER PATIENTS. (Eng.) Gudmand-Hoyer, E.; Frost, F.; Jensen, K. B.; Krag, E.; Rask-Madsen, J.; Rahbek, I.; *et al.* (Glostrup Univ. Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12 (5):611-613; 1977.

The use of cimetidine in the treatment of duodenal ulcer was assessed in a double-blind randomized trial in 58 patients. The patients in the treatment group received cimetidine (1 g/day) for 4 weeks, while the controls received inactive tablets. During the last 9 days, 18 of 30 cimetidine-treated patients were asymptomatic, in comparison with 5 of 28 controls ($p<0.005$). The antacid consumption, the number of days with pain, and the number of hours with pain also differed significantly in the two groups. Apart from a transient rash in one patient, no significant clinical side-effects were noted. The serum creatinine rose slightly in the cimetidine-treated patients.

6918 A PROSPECTIVE RANDOMIZED COMPARATIVE STUDY OF PROXIMAL SELECTIVE VAGOTOMY VS. SELECTIVE GASTRIC VAGOTOMY AND PYLOROPLASTY. (Eng.) Sawyers, J. L. (Nashville Metropolitan General Hosp., Nashville, TN). *Chir. Gastroenterol.* 11(1): 77-79; 1977.

A prospective randomized study was carried out in 63 men with chronic duodenal ulceration to compare proximal selective vagotomy with selective gastric vagotomy and Finney pyloroplasty. Only men with an ulcer intractable to medical therapy and without evidence of obstruction were admitted to the study. In follow-up periods of up to 2.5 yr, there was no operative mortality. No proven recurrent ulcer was found, but one patient with symptoms of recurrent duodenal ulcer 1 yr following proximal selective vagotomy was subjected to antrectomy. No recurrent ulcer was found in this patient at reoperation. Mild to moderate dumping occurred in 8 of 31 patients with selective vagotomy and pyloroplasty, in 1 of 32 patients after selective vagotomy and pyloroplasty, and in no patients with proximal selective vagotomy. This preliminary report suggests that proximal selective vagotomy is accompanied by less postgastrectomy sequelae than selective vagotomy and pyloroplasty and is equally effective in controlling the ulcer diathesis.

6919 OPERATIVE TREATMENT OF RECURRENCE AFTER VAGOTOMY AND DRAINAGE FOR DUODENAL ULCER, GASTRIC ULCER, AND ACID DYSPEPSIA WITHOUT ULCER. (Eng.) Johnson, J. A.; Giercksky, K. E. (Inst. Clinical Medicine, Univ. Tromso, 9000 Tromso, Norway). *World J. Surg.* 1(4):493-499; 1977.

Operative treatment to avoid recurrence of peptic ulcer was investigated, and the role of the insulin test for the evaluation of the completeness of the vagotomy was studied. Fifty-two operations were carried out in 44 patients with recurrent disease after vagotomy and drainage (38) or vagotomy without drainage (6). The initial vagotomy was done for duodenal ulcer (23), gastric ulcer (17), and acid dyspepsia without ulcer (4). The reoperations were 31 revagotomies, 11 Billroth II gastric resections, 2 gastrojejunostomies, and later, 4 gastric resections for another recurrence, 2 gastrojejunostomies for retention, and 2 operations for the dumping syndrome. After an observation period of 1-6 yr (mean 2.5 yr), the results were good in 22 patients, satisfactory in 20, and unsatisfactory in 2 patients. Of 42 patients with recurrent disease, 41 showed a significant increase of acid output during insulin stimulation before operative treatment of the recurrence. Of 31 revagotomized patients, 26 were insulin-test negative without later signs of recurrence. Five patients remained insulin-test positive, and four of these required gastric resection for another recurrence. This series demonstrates the therapeutic significance of complete vagotomy, and emphasizes the value of the insulin test for evaluation of the completeness of the vagotomy.

6920 LATE RESULTS OF PERFORATED DUODENAL ULCER TREATED BY SIMPLE SUTURE. (Eng.) Skovgaard, S. (Stenrosevej 19, 8330 Beder, Denmark). *World J. Surg.* 1(4):521-526; 1977.

To evaluate factors that influence ulcer diathesis after simple suture of perforated duodenal ulcer, a retrospective study was carried out in 156 patients who underwent follow-up evaluations 3-23 yr (mean 13 yr) after simple closure. Subsequent definitive ulcer surgery was indicated in 111 patients for severe recurrent dyspepsia. Bleeding, reperforation, or pyloric obstruction occurred in 14 patients. Among 33 patients with an ulcer history of less than 3 months prior to perforation, only 4 required further surgery while a subsequent operation was indicated in 107 of 123 patients with a longer ulcer history. Immediate definitive surgery is indicated for perforated duodenal ulcer in patients with ulcer symptoms for more than 3 months before perforation. Simple suture of the perforation is sufficient treatment for patients with a shorter ulcer history.

SMALL INTESTINE

6939 FOUR CASES OF POTASSIUM ENTEROPATHY. (Fre.) Diserens, H.; Gertsch, Ph.; Schneider, S.; Mosimann, R. (Service de chirurgie B, CHUV, CH1011 Lausanne, Switzerland). *Schweiz. Med. Wochenschr.* 107(34):1195-1198; 1977.

Stenosing ulceration or perforation of the distal and median small intestines occurred in four hypertension/coronary disease patients following p.o. potassium treatment. Three of the patients took enteric-coated KCl (2 g/day), and one took slow-release KCl. The KCl-induced symptoms appeared 3 weeks, 3 months, and 1 and 2 yr after the start of therapy. Clinically, the patients presented with colic symptoms, nausea, vomiting, and epigastralgia. All were subjected to surgery. Macroscopically, three patients had stenoses with ulceration of the small intestines. In one patient, the mucosa was amputated abruptly, and the richly vascularized submucosa was dissociated by a fibroblastic proliferation. The serosa was irregular and was infiltrated by lymphocytes, plasmacytes, and polynuclear cells. In another patient, the mucosa was not altered; however, fundic ulceration, vascular neoformations, and lymphoplasmacytic infiltrations were noted, and the entire wall was fibrotic. The patient who took slow-release KCl had generalized peritonitis caused by perforation of a distal jejunal loop that was fixed by two large adhesions to the mesosigmoid. The adhesions slowed intestinal transit, which led to KCl deposits, which in turn caused the lesions to develop.

6940 DIFFUSE CHRONIC ULCERATIVE JEJUNOILEITIS. USE OF JEJUNOSCOPY FOR DIAGNOSIS. (Fre.) Cerf, M.; Gouerou, H.; Marche, C.; L'Hirondel, C.; Debray, C. (Hopital Bichat, 170, boulevard Ney, F 75018 Paris, France). *Gastroenterol. Clin. Biol.* 1(6/7):571-576; 1977.

Diffuse chronic ulcerative jejunoileitis developed in a 51-yr-old man who was hospitalized for malabsorption with protein loss. The patient had recurrent diarrhea for 2 yr. Radiographs of the colon were normal, and an esogastroduodenal transit revealed only a small hiatal hernia; the small intestine appeared atrophic. A biopsy specimen of the small intestine contained villi that were much shorter than normal. The squamous epithelium was normal, pseudostratified, atrophic, and dissociated by inflammatory cells, with a thick and irregular brush border. The mucosa was interrupted by zones of superficial gastric metaplasia made up of mucous cells containing PAS-positive mucins. The chorion was thickened, and it contained lymphoplasmacytes and some eosinophilic polynuclear cells. Overall, the histological features of fibroinflammatory jejunitis with subtotal or partial villous atrophy were present. A 2-week treatment with ampicillin (2 g/day) and folic acid (40 mg/day) resulted in temporary improvement. After the patien was rehospitalized, a jejunoscopy was performed. Discrete inflammation of the gastric mucosa was seen The second half of the duodenum contained zones of patchy inflammation among thick, edematous folds. These zones were numerous, and they were found along the entire length of the segment of small intestine examined. Further biopsies during jejunoscopy showed that these inflammatory ulcerations did not have a specific character. An exploratory laparoto performed later revealed no macroscopic abnormaliti The patient finally improved after parenteral nutrition. A second jejunoscopy demonstrated improvemen of the intestinal mucosa with almost total disappea ance of the erosions. The diarrhea regressed after treatment with a gluten-free diet, antibiotics, and vitamin D.

6941 NONSPECIFIC CHRONIC ULCERATIVE JEJUNOILEITIS. REPORT OF A NEW CASE. (Fre.)

Belaiche, J.; Modigliani, R.; Modigliani, E.;
Galian, A.; Bernier, J. J. (Hopital Saint-Lazare,
107 bis, rue du Foubourg-Saint-Denis, F 75010,
Paris, France). *Gastroenterol. Clin. Biol.* 1(6/7):
553-560; 1977.

Nonspecific chronic ulcerative jejunoileitis
occurred in a 28-yr-old man with an 18-yr history
of severe malabsorption syndrome. Upon examination,
distinct exudative enteropathy was found. Duodenal
and jejunal biopsies were normal; small intestinal
transit revealed total disappearance of the mucosal
folds. Selective arteriography of the celiac trunk
and superior mesenteric artery was normal. A sub-
sequent exploratory laparotomy revealed numerous
mesenteric ganglia and induration along the mesen-
teric edge of the ileum. The patient was released,
but persistent cachexia and diarrhea required that
he be rehospitalized. Radiological examinations of
the gastrointestinal tract showed no stenoses, dilata-
tions, or ulcerations; duodenal and jejunal biopsies
were normal. The patient regained weight with paren-
teral nutrition, but the malabsorption syndrome con-
tinued. A second exploratory laparotomy revealed a
pathological small intestine, especially the second
half, and induration along its mesenteric border.
There were areas of marked stenoses near the median
part of the ileum. Resection with a 90-cm termino-
terminal anastomosis of the ileum was performed. The
specimen showed linear ulceration situated exclusive-
ly along the mesenteric border. These ulcerations
were surrounded by a dystrophic mucosa. Certain
crypts had a pseudoantral appearance. The lamina pro-
pria contained increased numbers of plasmacytes,
acrophages, and polynuclear cells. Despite therapy
ith prednisone (40 mg/day for 2 months) and tetra-
ycline (2 g/day for 6 weeks), no appreciable results
ere seen, and the exudative enteropathy persisted.

942 FECAL FAT, BILE ACID, AND STEROL EXCRETION
AND BILIARY LIPID CHANGES IN JEJUNOILEOS-
OMY PATIENTS. (Eng.) Faloon, W. W.; Rubulis, A.;
nipp, J.; Sherman, C. D.; Flood, M. S. (Highland
osp., South Ave., Rochester, NY 14620). *Am. J.
lin. Nutr.* 30(1):21-31; 1977.

ecal fat, bile acid, neutral sterol excretion,
iliary acid, phospholipid, and cholesterol were
tudied in 36 patients 6-12 months after jejuno-
leostomy for obesity to determine their interrela-
ionships. During the postoperative revaluation
dmission, all patients received a constant diet
ontaining 1,100 cal, 500 mg cholesterol, 65 g fat,
0 g carbohydrate, and 500 mg sodium. No relation
as observed between the degree of steatorrhea and
eight loss, although fecal fat excretion (range,
0.9-50.7 g/day) had increased in 34 of the 36
atients. Mean neutral sterol excretion in feces
as unchanged except in cholecystectomized patients.
o relationship was demonstrated between the observed
erum cholesterol decrease and fecal bile acid
ncrease (mean value 621 ± 96 mg/day from a control
lue of 206 ± 34 mg/day) or between serum cholesterol
evel and the sum of fecal fat and neutral sterol.
ecal excretion of cholic and deoxycholic acid
gether increased more than the total excretion of
chenodeoxycholic and lithocholic acid. Two major types of fecal excretion patterns were demonstrable; moderate fecal fat (24 g/day or less) was associated with a predominance of secondary bile acids (deoxycholic and lithocholic) in feces and in bile; high fecal fat (>24 g/day) was associated with predominantly primary bile acids (cholic and chenodeoxycholic). Thirty-six percent of the patients either had gallstones or had had a cholecystectomy, and, of 25 patients with normal cholecystograms, 4 developed stones and 5 had nonvisualization of the gallbladder 6-12 months postoperatively. Bile saturation ratio and lithogenic index did not change consistently postoperatively. No clear cut increase in lithogenic potential or in bile acid (lithocholic acid) hepatotoxic potential after jejunoileostomy was demonstrable.

SMALL INTESTINE

Malabsorption

977 TWO CASES OF ALPHA CHAIN DISEASE FROM
NIGERIA. (Eng.) Whicher, J. T.;
jdukiewicz, A.; Davies, J. D. (Westminster Hosp.
edical Sch., Kaduna, Nigeria). *J. Clin. Pathol.*
)(7):678-681; 1977.

ne first two cases of alpha chain disease from
ropical Central Africa are reported. Two men,
ged 60 and 14 yr, presented with a small bowel
ymphoma and malabsorption. The first patient
as treated with levamisole for a concomitant
trongyloides stercoralis infection. The bio-
emical and hematological findings were nonspecific
d were compatible with malabsorption. Patient 1
d a raised alkaline phosphatase level. Electro-
oresis did not reveal a paraprotein in either pa-
ent but a diffuse increase in gamma globulin run-
ng forward into the beta and alpha 2 was seen.
munoelectrophoresis was not diagnostic, and con-
rmation was obtained only by immunoselection
thods. Patient 1 showed the characteristic his-
logical features of the disease with a dense plas-
cytic infiltration of the lamina propria associated
th villous atrophy. Both patients were lost to
llow-up and treatment, but they died soon after
agnosis.

78 JEJUNAL MUCOSAL GAMMA GLUTAMYL TRANSFERASE
ACTIVITY IN COELIAC DISEASE. (Eng.)
irman, M. J.; Scott, B. B.; Toothill, C.; Los-
sky, M. S. (St. James' Hosp., Leeds, England).
t 18(6):484-487; 1977

In view of data suggesting that deficiency of gamma glutamyl transferase (GGT) may be the primary abnormality in the small intestinal mucosa of patients with celiac disease, this enzyme was measured in mucosal biopsies from celiac patients at different stages of treatment. The patients included four untreated patients, eight patients on a gluten-free diet but with abnormal jejunal histology, and nine patients on a gluten-free diet with normal mucosa. In 20 control patients, the GGT level was 0.6-2.6 IU/g. The GGT level fell below the control range in only one of the 21 celiac patients and in one of the nine treated patients with normal mucosa, suggesting that deficiency of this enzyme has no primary role in the etiology of celiac disease.

6979 ENTEROCHROMAFFIN CELLS IN THE DUODENAL MUCOSA OF CHILDREN WITH COELIAC DISEASE. (Eng.) Challacombe, D. N.; Robertson, K. (Children's Res. Unit, Taunton, England). *Gut* 18(5):373-376; 1977.

To examine the hypothesis that hyperplasia and/or hyperactivity of the enterochromaffin (EC) cells could explain raised blood 5-hydroxytryptamine (5-HT) and urinary 5-hydroxyindoleacetic acid (5-HIAA) in patients with untreated celiac disease, a cell counting technique was used to count EC cells in the duodenal mucosa of 10 children with celiac disease and in 10 controls. Significantly greater numbers of EC cells were found in children with celiac disease ($p<0.001$). In four children with a clinical history suggestive of celiac disease, but with minor histopathologic changes in the duodenum, gluten challenge resulted in increased numbers of EC cells. Abnormalities of 5-hydroxytryptamine metabolism in celiac disease may result from hyperplasia of EC cells in the small intestine.

6980 RELATIVE LACTOSE INTOLERANCE: A CLINICAL STUDY OF TUBE-FED PATIENTS. (Eng.) Walike, B. C.; Walike, J. W. (Sch. Medicine, Univ. Michigan, Ann Arbor, MI). *JAMA* 238(9):948-951; 1977.

Lactose tolerance was studied in 16 patients receiving nasogastric tube feedings following surgery for head or neck carcinoma. Two liquid diets, differing only in the presence or absence of lactose (75 g/l), were administered for 8-20 days in a double-blind crossover study. Increased stool frequency, decreased stool consistency, and more frequent flatulence, borborygmi, and distention were found with the lactose diet, although classic lactose intolerance (plasma glucose rise <26 mg/dl) occurred in only two patients. Differences between amounts and times of peak rise following the glucose tolerance test and lactose tolerance test for each patient indicated the advisability of locating patients on a continuum of ability to hydrolyze lactose. The results indicate that lactose should be reduced or eliminated from tube-feeding diets to improve patient tolerance and comfort and to reduce diarrhea.

6981 POSSIBLE PATHOGENETIC MECHANISMS PRODUCING BOVINE MILK PROTEIN INDUCIBLE MALABSORPTION: A HYPOTHESIS. (Eng.) Liu, H. Y.; Giday, Z.; Moore, B. F. (2104 Vinewood Blvd., Ann Arbor, MI 48104). *Ann. Allergy* 39(1):1-7; 1977.

In view of the well known smooth muscle-stimulating effect of some of the mediators of anaphylaxis, it was determined whether clinically evident histaminergic signs could be concurrently induced along with those of intestinal malabsorption and hyperperistalsis by challenging atopic patients with bovine milk or milk proteins. The feeding of bovine milk to five highly allergic pediatric patients with bilateral family histories of atopy led to transient malabsorption of glucose and fat as well as systematic autonomic functional changes that may be attributable to pharmacologic actions of histamine and/or acetylcholine. During allergic reactions, endogenously released smooth muscle-stimulating neuromediators could provide rapid propulsion of nutrients through the absorbing portion of the gut, leading to suboptimal absorption; it is also hypothesized that bovine milk-inducible malabsorption in the atopic patients has an immunopharmacologic basis in its pathogenesis.

6982 INTESTINAL PERFUSION STUDIES IN TROPICAL SPRUE. 2. MOVEMENT OF WATER AND ELECTROLYTES. (Eng.) Hellier, M. D.; Bhat, P.; Albert, J.; Baker, S. J. (St. Thomas' Hosp., London S.E. 1, England). *Gut* 18(6):480-483; 1977.

Jejunal sodium and water absorption was investigated in 10 normal Indians and in 11 patients with chronic tropical sprue. Normal saline and solutions containing amino acids and dipeptides were studied. In both groups, little absorption of sodium and water from normal saline was seen. Mean water and sodium absorption from the free amino acid or dipeptide solutions showed no significant difference between the groups and was similar to absorption from normal saline. These results differ from data obtained in normal English subjects in whom significant stimulation of sodium and water absorption was seen at these concentrations. In some subjects in both groups, net secretion was observed. However, no correlation was seen between mucosal histology or luminal bacteriology and sodium or water movement. These findings in patients with chronic tropical sprue are similar to findings in normal Indians and suggest that jejunal handling of sodium and water is abnormal when compared with normal English subjects, but that the mucosa is not in a secretory phase as seen in certain other diarrheal states or in the acute early phase of sprue.

LARGE INTESTINE

6997 METASTATIC COLON CARCINOMA SIMULATING PRIMARY BILE DUCT CARCINOMA VIA ENDOSCOPIC CHOLANGIOGRAPHY. (Eng.) Nagler, J.; Rochwarger, A. M. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *Gastrointest. Radiol.* 2(1):75-76; 1977.

The case of a 59-yr-old man with metastatic colon carcinoma simulating primary bile duct carcinoma is presented. The radiographic similarities via endoscopic retrograde cholangiopancreatography included bile duct narrowing and mucosal destruction. A distinguishing feature, however, was the failure of the intrahepatic biliary tree to dilate. When an area of irregular narrowing of a bile duct with mucosal destruction is demonstrated on a cholangiogram, metastatic disease from the colon, gallbladder, pancreas, or lymphoma should be considered in the differential diagnosis along with primary bile duct carcinoma.

6998 ACCUMULATION OF BONE-SEEKING RADIONUCLIDES IN LIVER METASTASIS FROM COLON CARCINOMA. (Eng.) Garcia, A. C.; Yeh, S. D. J.; Benua, R. S. (Cornell Medical Coll., New York, NY). *Clin. Nucl. Med.* 2(8):265-269; 1977.

Liver and bone scans were carried out in 15 colon cancer patients with metastasis to the liver. Seven of these showed accumulation of bone seeking radionuclides in the liver at the site of a defect in the scan. Such accumulation was found in two diphosphonate, in one pyrophosphate, and in six ^{18}F scans. This is apparently the first series to report localization of ^{18}F in intrahepatic metastasis from colon cancer.

6999 PRELIMINARY LONGITUDINAL STUDIES OF SERUM POLYAMINES IN PATIENTS WITH COLORECTAL CARCINOMA. (Eng.) Nishioka, K.; Romsdahl, M. M. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Cancer Lett. (Amsterdam)* 3(3/4):197-202; 1977.

Serum polyamine levels in 10 patients with colorectal carcinoma or Gardner's syndrome who were examined >1 yr were found to reflect the disease status. In a patient with multiple adenocarcinoma of the colon (stage B) who underwent a total colectomy, preoperative levels of spermidine and spermine were slightly elevated above the normal values of 0.33 and 0.06 nmol/ml serum, resp., but the preoperative putrescine level (about 1.4 nmol/ml) was greatly elevated above the normal level of 0.33 nmol/ml. An 11-day postoperative sample showed even higher polyamine levels. Over the next 20 months, however, serum polyamine levels decreased to the normal range in this subject, who currently has no clinical evidence of disease.

A patient with adenocarcinoma of the ascending colon, four with stages B and C disease, and one with benign bowel disease (villous adenoma) who underwent successful surgery showed polyamine profiles similar to that of the above patient, except that the villous adenoma patient showed normal serum polyamine levels before surgery. Preoperative serum from a rectal adenocarcinoma patient showed slightly elevated putrescine (0.40 nmol/ml) and spermidine (0.43 nmol/ml) levels. Metastasis to the liver was found at colostomy, and chemotherapy with 5-fluorouracil was instituted. Serum analysis 8 days later showed a high putrescine level (almost 1.0 nmol/ml) that subsequently declined. Despite no clinical evidence of disease 12 months after surgery, a persistent slight elevation of spermidine suggested the presence of a slow-growing tumor; an abnormal liver scan and a slightly elevated alkaline phosphatase level were found 15 months after surgery, and the disease is currently progressive. In a patient with Gardner's syndrome, a preoperative serum sample prior to ileostomy showed a high putrescine level (about 2 nmol/ml) that gradually declined after surgery. However, at 21 months, the patient developed partial bowel obstruction, and the putrescine level was elevated (0.45 nmol/ml). A final serum sample obtained 1 month before death (exploratory laparotomy had indicated desmoid-type fibrosarcoma) showed high polyamine levels (putrescine and spermidine >1.0 nmol/ml and spermine about 0.6 nmol/ml). The results suggest that sequential determination of serum polyamine levels correlates highly with the clinical course in patients with colorectal carcinoma.

7000 CLINDAMYCIN-ASSOCIATED COLITIS IN CHILDREN: A PROSPECTIVE STUDY AND A NEGATIVE REPORT. (Eng.) Randolph, M. F.; Morris, K. E. (70 Deer Hill Ave., Danbury, CT 06810). *Clin. Pediatr.* 16 (8):722-725; 1977.

A prospective study was carried out over a 31-month period in 1,484 children to assess the risk of colitis associated with clindamycin therapy. The patients received clindamycin (8-16 mg/day, p.o.) for 10 days for the treatment of beta hemolytic streptococcal pharyngitis, acute cervical adenitis, impetigo, acne, or cellulitis. Children who were taking another antibiotic; had a known allergy to lincomycin or clindamycin; or had a personal or family history of irritable bowel, colitis, food allergies, milk intolerance, melena, or bloody stools were excluded. Diarrhea (≥5 watery bowel movements/24 hr) occurred in 38 children; this began on the fourth to eighth day of drug use and ended within 8 days (average 5 days) after clindamycin was stopped. In 90 stool samples from these patients, no occult blood was present, mucus was scant to moderate, and fecal films stained with methylene blue were negative for WBC. The results suggest that clindamycin is better tolerated by children than by adults.

7001 PERFORATION OF THE SIGMOID COLON DURING PREGNANCY: A RARE COMPLICATION OF ENDOMETRIOSIS: CASE REPORT. (Eng.) Clement, P. B. (Dept. Pathology, Univ. British Columbia, Vancouver, British Columbia, Canada). *Br. J. Obstet. Gynaecol.* 84(7):548-550; 1977.

The case of a 28-yr-old woman in whom perforation of the sigmoid colon occurred during the 37th week of pregnancy is reported. There was almost complete replacement of the bowel wall by endometriotic tissue showing extensive decidualization of its stroma. This condition appears to be a very rare complication of endometriosis. The effects of pregnancy upon endometriosis are briefly reviewed.

7002 COMPARISON OF BARIUM ENEMA AND COLONOSCOPY IN THE DETECTION OF SMALL COLONIC POLYPS. (Eng.) Thoeni, R. F.; Menuck, L. (Univ. California, Sch. Medicine, San Diego, CA). *Radiology* 124(3): 631-635; 1977.

Two hundred and ten patients were examined by barium enema (both conventional and double-contrast technique) and colonoscopy to determine and compare the accuracy of each method in the detection of small colonic polyps. Two hundred and nineteen polyps were found in 112 patients; of these, 142 were diagnosed by both methods and 50 polyps were identified by colonoscopy and not detected by barium enema. Colonoscopy failed to detect 27 polyps, 21 of these because the area could not be reached by the colonoscope. The usual cause of error in the other cases was that bleeding or a large fold obscured the lesion. Single-contrast barium enema missed 33 and double-contrast barium enema missed 17 polyps. There were five malignant polyps 1 cm or less in diameter, the smallest being 5 mm, among 112 patients studied. All five small carcinomas were detected by direct double contrast examination. Double-contrast barium enema offers a definite advantage in the right colon. In general, the two methods are complementary for evaluating the colon.

Ulcerative Colitis

7062 IMMUNOHISTOCHEMICAL IDENTIFICATION OF LYSOZYME IN INTESTINAL LESIONS IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Klockars, M.; Reitamo, S.; Reitamo, J. J.; Moller, C. (Fourth Dept. Medicine, Unioninkatu 38, 00170 Helsinki 17, Finland). *Gut* 18(5):377-381; 1977.

The distribution of lysozyme (LZM)-containing cells was studied immunohistochemically in the intestinal lesions of 15 patients with ulcerative colitis, 7 patients with Crohn's disease, and 24 controls. LZM was identified in ulcerative colitis in granulocytes, monocytes, and macrophages of the intestinal lamina propria. In contrast with findings in normal colon or rectum, in ulcerative colitis LZM was also detected in some mucosal crypt cells and metaplastic Paneth cells. In both ulcerative colitis and Crohn's disease, LZM was present in inflammatory cells of crypt abscesses. In Crohn's disease, intense LZM staining was seen in epitheloid cell granulomas. The present observations permit one explanation for the raised concentration of serum LZM in patients with ulcerative colitis and Crohn's disease. The fate of LZM-containing inflammatory cells and their enzymic content may differ in these two diseases. Fixed mononuclear phagocytes may lose their enzymic content into the circulation, whereas the granulocytes in ulcerative colitis may ultimately reach the colonic lumen by diapedesis.

7063 INTENSIVE TREATMENT IN SEVERE ACUTE ATTACKS OF ULCERATIVE COLITIS. (Eng.) Schjonsby, H.; Heimann, P.; Kremer, D.; Nordgard, K.; Raugstad, T. S.; Ringheim, F.; Stray, O. (Haukeland Sykehus, Univ. Bergen, Bergen, Norway). *Acta Med. Scand.* 603(Suppl.):43-46; 1977.

The results of intensive treatment including steroids and early surgery in severe colitis in the period 1971-1975 were compared with the results from the period 1966-1970, when systematic intensive therapy was not given. The period of preoperative medical treatment was reduced on average from 31 to 17 days. Approximately half the patients went into remission in each period. In the period 1971-1975 (23 patients), there was no mortality during the acute attacks or in the subsequent follow-up period. In the period of 1966-1970, the immediate mortality in 30 patients was 10%. One patient died 6 yr later at the age of 81 during a relapse of the colitis; the overall mortality was 13.3%. The change in overall mortality was mainly due to reduced operative mortality. In the first period, the operative mortality in 15 patients was 20%; whereas, none of 11 patients died after surgery during the second period.

7064 THE EFFECT OF PREDNISOLONE ON LEUCOCYTE FUNCTION IN MAN: A DOUBLE BLIND CONTROLLED STUDY. (Eng.) Clarke, J. R.; Gagnon, R. F.; Gotch, F. M.; Heyworth, M. R.; Maclennan, I. C. M.; Truelove, S. C.; *et al.* (Radcliffe Infirmary, Oxford OX2 6HE, England). *Clin. Exp. Immunol.* 28(2):292-301; 1977.

The effect of prednisolone on WBC numbers and function and on plasma cell population in rectal biopsies was studied in 20 patients with ulcerative colitis in remission. The patients were randomly allocated to two equal groups, one receiving prednisolone (20 mg i.v.; then tablets, 40 mg daily) and the other a dummy preparation (sterile saline i.v.; then lactose tablets). The mean lymphocyte count fell from 1,738 cells/mm to 501 cells/mm 4 hr after prednisolone was given ($p>0.001$) but by 24 hr was significantly elevated to 2,399 cells/mm ($p>0.02$); thereafter it returned to normal levels. Similar fluctuation was observed in lymphocytes forming spontaneous rosettes with sheep cells erythrocytes sensitized with human anti-D antiserum, and erythrocytes incubated with rabbit anti-sheep erythrocyte immunoglobulin, and with an equal volume of fresh AKR male mouse serum. The mitotic response to a submaximal stimulating dose of phytohemagglutinin (PHA) was significantly depressed ($p>0.01$) 4 hr after steroid administration but returned to normal by 24 hr. The spontaneous and PHA-induced lymphocyte-mediated cytotoxic activity was significantly depressed after the injection of 20 mg steroid ($p>0.05$ and $p>0.001$, resp.) and remained depressed at 7 days. K-cell cytotoxicity did not follow the general pattern and was lowest after 24 hr of steroid administration and remained depressed 7 days after cessation of steroid administration. No significant differences in the sigmoidoscopic or histological appearances of the rectal mucosa were observed between the two groups. No significant changes occurred in any of the above assays in the control group. Polymorphonuclear WBC counts were elevated in the patients on steroid therapy and in the control group but the control group returned to normal values by 24 hr. Prednisolone is not likely to lead to bacterial infection or is it likely to be important in the treatment of ulcerative colitis.

PANCREAS

Pancreatitis

7075 PANCREATIC REFLUX INTO WIRSUNG'S DUCT DURING PEROPERATIVE BILIARY RADIOMANOMETRY IN ACUTE AND CHRONIC PANCREATITIS. (Fre.) Lataste, J.; Albou, J. C. (Centre Hospitalier Intercommunal, 94000 Creteil, France). *J. Chir. (Paris)* 113(3):255-262; 1977.

Pancreatic reflux during biliary radiomanometry (RM) occurs frequently in patients with acute and chronic pancreatitis. Of 78 acute pancreatitis patients explored by RM, reflux into Wirsung's duct occurred 22 times. In 7 patients, reflux was due to distal obstruction (3 enclaved calculi, 4 odditis); in 15, it was due to cholelithiasis. In one enclaved calculus patient, Santorini's duct was totally blocked, and the patient died of acute hemorrhagic pancreatitis in 48 hr. The other two enclaved calculus patients were cured after sphincterotomy. Prognosis depends on the completeness of the pancreatic blockage. Of 31 complete blockages of the sphincter of Oddi, 6 cases of acute pancreatitis and 1 of edematous acute pancreatitis resulted, but of 22 incomplete blockages (18 odditic, 4 with a permeable Santorini's duct), only 2 cases of acute pancreatitis were noted. Wirsung's duct was dilated markedly in three cases of acute pancreatitis. Of 138 patients who underwent RM for chronic or subacute recurrences of pancreatitis, radiological reflux in Wirsung's duct occurred in 19 patients. An obstacle in the sphincter of Oddi was noted in nine patients (8 odditis, 1 enclaved calculus), six of whom had a dilated Wirsung's duct. The duct was dilated in only 2/10 patients when no odditic obstacle was present. Sphincterotomy is recommended in cases of chronic pancreatitis associated with gallstones.

7076 HYPERCALCITONEMIA AS A CAUSE OF HYPOCALCEMIA IN ACUTE PANCREATITIS.

(Eng.) Berstad, T.; Onstad, A.; Gautvik, K. M. (Deaconess Hosp., Oslo, Norway). *Chir. Gastroenterol.* 11(1):147-151; 1977.

The cases of two patients (a 27-yr-old woman and a 37-yr-old alcoholic man) with acute pancreatitis and hypocalcemia in whom hypercalcitonemia was present are presented. The diagnosis of acute pancreatitis was made on the basis of clinical examination and verified by changes in the serum amylase, serum electrolytes, blood glucose, and for patient 1, also by peroperative examination of the pancreas. In the acute phase of the disease, both patients showed elevated serum calcitonin concentrations (2.16 ng/ml for patient 1 and 0.60-0.56 for patient 2), and the most marked hormone elevation was associated with the most pronounced hypocalcemia (7.3-4.2 mg% for patient 1 and 8.4 mg% for patient 2). In patient 1, normal serum levels of parathyroid hormone (0.10 ng/ml) were found, while this hormone was increased in the other patient (3.4 ng/ml). The increases in serum concentrations of calcitonin and parathyroid hormone were transient and confined to the acute period of the disease, thereby ruling out the possibility of chronic endocrine diseases underlying these findings. Calcitonin and parathyroid hormone levels returned to normal in parallel with the normalization of the amylase values and in parallel with a general improvement of the condition of the patients. To determine whether glucagon elevates the serum calcitonin level, patient 1 and two healthy subjects received an i.v. infusion of glucagon (3 mg). The serum values of calcitonin did not change significantly in controls or in the patient. The results suggest a causal relationship between increased calcitonin concentrations and hypocalcemia.

7077 SURGICAL TREATMENT OF ACUTE HEMORRHAGIC PANCREATITIS. REPORT OF 75 CASES.

(Fre.) Lataste, J.; Serpault, P. (Hopital intercommunal de Creteil, 40, boulevard de Verdun, 94000 Creteil, France). *J. Chir. (Paris)* 113(5/6):447-456; 1977.

A study of 75 patients with acute hemorrhagic pancreatitis (AHP) showed that in 39, it was associated with a biliary lesion. Etiologically, AHP was due to primary pancreatitis (35), embedded calculus in the ampulla of Vater (11), calculus in the lower bile duct (8), vesicular lithiasis (13), sclerous odditis (2), chronic pancreatitis (1), and postsphincterotomy pancreatitis (5). Mortality was higher in patients with biliary pancreatitis and a blockage of the sphincter of Oddi. Seven of the 11 patients with embedded calculi died, as did 4/5 postsphincterotomy patients. Description of the pancreatic lesions is difficult because of the anatomical location of the pancreas; early surgical excision is not recommended, as it is too dangerous. Overall (in addition to the 4 postsphincterotomy patients), 30 patients died postoperatively, 19 during the first week. Forty-one patients were cured; 11 required secondary sequestrectomy after the 20th day, but 30 did not, despite voluminous hematomas. Immediate surgery is recommended to uncover a suspected biliary lesion. This includes cholecystectomy (which can disclose certain nonpalpable calculi), radiomanometry of the common bile duct, and, if necessary, sphincterotomy.

7078 RELATIONSHIP BETWEEN THE MORPHOLOGIC APPEARANCE OF PANCREATIC CALCULI AND PANCREATIC FUNCTION IN CHRONIC CALCIFYING PANCREATITIS.

(Eng.) Wakabayashi, A.; Hashihira, S. (Osaka Medical Coll., Takatsuki, Osaka 569, Japan). *Am. J. Gastroenterol.* 67(1):47-53; 1977.

The relationship between the morphologic appearance of pancreatic calculi and pancreatic function in chronic calcifying pancreatitis was studied in 12 patients with large calculi (LC) and 7 patients with diffuse minute calculi (DMC). The cause of the calculi could not be determined in 66.7% of the LC cases, whereas in all of the DMC cases, the daily ingestion of >540 ml of sake for >10 yr was shown to be the cause. The LC were located mainly in the head and body of the pancreas, but the DMC were distributed in the head, body, and tail. Disturbances in pancreatic exocrine and endocrine functions, as measured by the pancreozymin-secretin test and the 50-g p.o. glucose-tolerance test, were less severe in cases of LC than they were in cases of DMC. All of the DMC patients were diabetic, but only five of the LC patients were diabetic, with another five being borderline for p.o. glucose loading and the remaining two patients being normal. In the pancreozymin-secretin test, the range of values for volume output for 60 min after secretin (ml), maximum bicarbonate concentration (mEq/l), bicarbonate output for 60 min after secretin (mEq), and amylase output for 100 min after pancreozymin (log U) were 23-133, 19.4-92.4, 0.58-8.88, and 4.6284-5.2210, resp., for the LC patients and 47-93, 18.0-60.2, 0.39-4.12, and 4.3820-5.1987, resp., for the DMC patients. Normal ranges were 50-204, 72.1-144.5, 1.59-21.03, and 5.0219-5.7595, resp. The two types of pancreatic calculi were clearly distinguishable, indicating marked differences in the pathophysiological process. Thus, they cannot be regarded as a single disease entity.

7079 ARTERIAL HEMORRHAGE DURING THE EVOLUTION OF CHRONIC PANCREATITIS. (Fre.) Guntz, M.; Albaret, P.; Ben Bouali, A.; Baudet, P.; Cherruaud, D. (Clinique Medicale A, C.H.U., 49000 Angers, France). *Ann. Chir.* 30(10):836-838; 1976.

Problems in identifying the source of the arterial hemorrhage due to portal hypertension that occurs during the evolution of chronic pancreatitis are exemplified by the case histories of two patients. A 63-yr-old patient with a 10-yr history of calcifying chronic pancreatitis had subacute attacks of pancreatitis with hyperamylasemia. Paraclinical examinations revealed calcifications typical of lithiasis of Wirsung's duct, distinct pneumatization of the common bile duct, enlargement of the duodenum, and total absence of selenomethionine fixation by the pancreas. Extensive hematemesis requiring blood transfusions occurred. Surgery revealed a pseudocyst of the hemorrhagic pancreatic head. Sclerosis ductal and parenchymatous calcifications, and erosion of the large intrapancreatic branch of the gastroduodenal artery and bile duct were noted. The patient was cured following a cephalic duodenopancreatectomy. The other patient, a 42-yr-old alcoholic with calcifying chronic pancreatitis, presented with digestive hemorrhaging. Arteriography of the celiac trunk disclosed an aneurysm of the juxtahiliary splenic artery. The patient was cured following a caudal splenopancreatectomy. A review of 84 literature cases revealed that digestive hemorrhaging was mainly due to ulceration in the walls of the pancreatic artery, pseudocyst, or calcification and rarely to a ruptured aneurysm of an intra- or juxtapancreatic arterial branch that opened into the pancreatic duct.

LIVER AND BILIARY TRACT

7084 ANTIPYRINE, PARACETAMOL, AND LIGNOCAINE ELIMINATION IN CHRONIC LIVER DISEASE. (Eng.) Forrest, J. A. H.; Finlayson, N. D. C.; Adjepon-Yamoah, K. K.; Prescott, L. F. (Royal Infirmary, Edinburgh EH3 9YW, England). *Br. Med. J.* 1(6073):1384-1387; 1977.

The plasma half-lives of p.o. administered antipyrine, paracetamol, and lignocaine were measured in 23 patients with stable chronic liver diseases of varying severity. Fifteen patients received all three drugs, and 19 received at least two. The test drugs were administered consecutively 2-3 days apart over 7-10 days and usually in the sequence lignocaine (400 mg), antipyrine (18 mg/kg), and paracetamol (1.5 g). The half-life of paracetamol was abnormally prolonged in 9 out of 17 patients (mean 2.9 hr, normal 2.0 hr), of antipyrine in 10 of 19 patients (mean 30.4 hr, normal 12.0 hr), and of lignocaine in 19 of 21 patients (mean 6.6 hr, normal 1.4 hr). Prolongation of the half-lives of all three drugs was significantly correlated with an increase of the vitamin-K_1-corrected prothrombin time ratio and a reduction in serum albumin concentration. There was no correlation with serum bilirubin concentration or serum alanine aminotransferase activity. This finding suggests that impaired drug elimination was related to depressed hepatic protein synthesis. Considerable prolongation of the half-life of one drug was invariably associated with delayed elimination of the others. The half-life of lignocaine, however, was always the most prolonged and was a highly sensitive indicator of hepatic dysfunction. The pharmacokinetic characteristics of a drug as well as the severity of liver disease should be taken into account when considering drug dosage in patients with chronic liver disease.

7085 PRACTICAL ENZYMATIC DIAGNOSIS IN GASTROENTEROLOGY. (Ger.) Camenisch, R.; Filippini, L. (Gastroenterologische Abteilung, Kantonsspital, 6004 Lucerne, Switzerland). *Praxis* 66(7):200-205; 1977.

Possibilities of the enzymatic differential diagnosis of gastrointestinal diseases are reviewed. Increased transaminase activity is a feature of the hepatitis syndrome, and a persistent, considerable rise in alkaline phosphatase (AP) activity is characteristic of the cholestatic syndrome. However, the severity of disease can be determined only from the prothrombin time, which is reduced by vitamin K in hepatitis and normalized by this vitamin in cholestasis. Severe chronic liver diseases are characterized by an increased γ-globulin level. γ-Glutamyl transpeptidase is highly specific for anicteric liver damage, and, therefore, it should replace the BSP test, which is not without risks. The urine amylase test is of diagnostic value in acute pancreatitis, even though an increase of amylase activity is not specific for primary pancreatic diseases. The fecal chymotrypsin test is suitable for screening chronic pancreatic diseases. Idiopathic and symptomatic pernicious anemia (in the malassimilation syndrome or in postgastrectomy patients) usually is characterized by significantly increased lactate dehydrogenase activity.

7086 ANGIOGRAPHY IN THE DIAGNOSIS OF LIVER DISEASE IN CHILDREN. (Eng.) Rosch, J.; Mayer, B. S.; Campbell, J. R.; Neerhout, R. C. (Univ. Oregon Health Sciences Center, 3181 S.W. Sam Jackson Park Rd., Portland, OR 97201). *Radiol. Clin. (Basel)* 46(5):321-339; 1977.

A total of 75 hepatic angiograms were taken in 64 children with normal (23 cases) or diseased (41 cases) livers. The latter comprised diffuse inflammatory or degenerative disease (hepatitis or cirrhosis, 10 cases), primary malignant tumor (7), diffuse infiltrative neoplasm (2), metastatic tumor (7), benign tumor (4), abscess (4), and extrahepatic portal occlusion (7). The angiographic diagnosis was accurate in 42/44 patients in whom the diagnosis was proved by surgery, autopsy, and/or biopsy. A hypervascular, solitary, inflamed, necrotic liver cyst was misdiagnosed as a tumor with internal bleeding or necrosis, and a false-negative diagnosis was made in a 2-yr-old boy with a Wilms' tumor. Primary malignant tumors had characteristic angiographic patterns, whereas diffuse neoplasms were relatively avascular and caused stretching, displacement, and luminal irregularities of intrahepatic arteries and, occasionally, their occlusions. Non-neoplastic masses such as benign cysts or liver abscesses were manifested by avascular defects with displaced surrounding branches and, in liver abscesses, by regional inflammatory hypervascularity. In chronic hepatitis with predominant fibrosis and hepatomegaly, elongation, stretching, and thinning of major and medium-sized arteries appeared along with poor peripheral branch filling, particularly in the late stages of disease. Cirrhosis, often showed increased arterial flow to the liver with enlarged and characteristically tortuous corkscrew arteries. In patients with extrahepatic portal obstruction, typical findings were seen during the venous phase of tolazoline-augmented superior mesenteric angiography. Portal veins and the upper part of the mesenteric veins in two patients were replaced by varying numbers of hepatopetal collaterals that entered middle-sized intrahepatic portal branches. Hepatofugal collateral vessels shunting portal blood to both vena cava systems were also present in varying degrees.

7087 DIAGNOSIS OF IMMUNOPATHOLOGICAL REACTIONS IN LIVER DISEASES. (Ger.) Meyer zum Buschenfelde, K. H. (II. Medizinische Klinik und Poliklinik, Johannes-Gutenberg-Universitat Mainz, Postfach 3960, 6500 Mainz, W. Germany). *Med. Klin.* 71(36):1401-1412; 1976.

Studies and observations of the diagnostic relevance of immunopathological reactions in liver diseases are reviewed. Study of the humoral immune reactions is necessary for the diagnosis and differential diagnosis of primary biliary cirrhosis, chronic active hepatitis, and cryptogenic cirrhosis. The detection of hepatitis B surface antigen (HBsAg) and HBs antibody has improved the differentiation between virus-induced and autoimmune hepatitis. Along with these diagnostic markers, functional study of the thymus-dependent immune system, detection of cellular immune reactions to liver antigens and HBAg components, and localization of IgG on the hepatocyte membrane have been of great value in studies of the pathogenesis of chronic hepatitis. The presence of antibodies to the internal mitochondrial membranes of various tissues is one of the major characteristics of primary biliary cirrhosis; these antibodies are found in >90% of the patients. Consequently, they help differentiate between the intrahepatic and extrahepatic obstruction syndromes and among the various intrahepatic cholestases.

7088 ALPHA$_1$-FETOPROTEIN IN NEONATAL HEPATOBILIARY DISEASE. (Eng.) Andres, J. M.; Lilly, J. R.; Altman, R. P.; Walker, W. A.; Alpert, E. (Massachusetts General Hosp., Boston, MA 02114). *J. Pediatr.* 91(2):217-221; 1977.

The value of quantitating serum alpha$_1$-fetoprotein (AFP) in distinguishing the neonatal hepatitis syndrome from biliary atresia was investigated in 52 neonates and infants with various hepatobiliary disorders, including neonatal hepatitis syndrome (group I), biliary atresia (group II), and other hepatopathies such as choledochal cyst (group III). The mean serum AFP concentration in patients with neonatal hepatitis (51.1 ± 25.8 μg/ml) was significantly greater than the mean concentrations in the other two groups (9.8 ± 1.8 and 3.8 ± 2.3 μg/ml in groups II and III, resp.). There was no significant difference between the mean serum AFP concentrations in patients with biliary atresia and in group III patients. Patient age was noted to be an important factor; serum AFP levels greater than 35 μg/ml in infants 1-4 months of age suggested the diagnosis of neonatal hepatitis syndrome. Serum AFP levels below 10 μg/ml in infants less than 4 months of age suggested the diagnosis of biliary atresia or hepatopathies other than neonatal hepatitis. However, the variable and significant overlapping of serum AFP values between 10 and 35 μg/ml limit the diagnostic value of this test.

7089 RADIOIMMUNOLOGICAL DETERMINATION OF α-FETOPROTEIN IN HEPATOBILIARY DISEASES.

(Fre.) Joubaud, F.; Cheguillaume, J.; Baudet, P.; Ben Bouali, A.; Boyer, J.; Dao, M. (Clinique Medicale A, C.H.U. Angers, Angers, France). *Rev. Fr. Gastroenterol.* 126(2):13-21; 1977.

Radioimmunoassay was used to measure serum levels of α-fetoprotein (AFP) in 364 patients with various hepatobiliary diseases. Control levels in 126 normal subjects averaged 3.4 ng/ml. In 51 patients with a primary hepatocarcinoma, AFP levels averaged 1,654.4 ng/ml, but in 31 patients with a secondary liver tumor, they averaged only 15.8 ng/ml. Some gastric or prostatic cancers caused moderate elevations in AFP. Levels were normal or slightly elevated in 201 patients with cirrhosis and moderately elevated (>100 ng/ml) in 17/23 patients with viral hepatitis. The latter values were transitory, and they reflected hepatic recovery and regeneration. Diseases such as biliary tumor, alcoholic hepatitis, or lithic cholangitis did not affect AFP levels.

7090 SIGNIFICANCE OF ANTIALBUMIN ANTIBODIES, A NEW SYSTEM OF ANTIBODIES IN CHRONIC LIVER DISEASES.

(Fre.) Buligesco, L.; Lenkei, R.; Ciontea, M.; Dan, E. M. (Medical Clinic, Fundeni Hosp., Bucharest, Rumania). *Gastroenterol. Clin. Biol.* 1(5):487; 1977.

The presence of antialbumin antibodies (AAA) in 69 patients with liver diseases (persistent chronic hepatitis, 12; types A and B aggressive chronic hepatitis, 33; compensated hepatic cirrhosis, 17) was determined by immunodiffusion or passive hemagglutination. There was a correlation between the presence of AAA, and the etiology, degree of evolution, change in hepatic function, and intensity of the immunological process. AAA was found in the serum of 16.6% of the persistent hepatitis patients, 75.75% of the aggressive hepatitis patients, and 85% of the hepatic cirrhosis patients. The overall incidence was 68.11%. The presence of AAA correlated with a decrease in serum albumin, BSP clearance, and an increase in γ-globulins, immunoglobulins, AAN and AMI.

7091 ELIMINATION OF CANRENONE IN CONGESTIVE HEART FAILURE AND CHRONIC LIVER DISEASE.

(Eng.) Jackson, L.; Branch, R.; Levine, E.; Ramsay, L. (Bristol Royal Infirmary, Bristol, England). *Eur. J. Clin. Pharmacol.* 11(3):177-179; 1977.

Because spironolactone is frequently prescribed in chronic liver disease and in congestive heart failure, the elimination half-life ($T_{1/2}$) of canrenone (the principal unconjugated metabolite of spironolactone) was determined in seven patients with congestive heart failure and five patients with chronic liver disease. The $T_{1/2}$ of canrenone was 59 hr (range 32-105 hr) in the patients with chronic liver disease and 37 hr (range 19-48 hr) in the patients with congestive heart failure. In comparison, the $T_{1/2}$ in normal subjects was 13.5-24 hr in previous reports and 20.5 hr in normal subjects in the present study. However, there was no evidence of greater cumulation of canrenone in the plasma of those patients with a prolonged $T_{1/2}$.

7092 PLASMA DISAPPEARANCE OF INTRAVENOUSLY INJECTED RADIOLABELLED GLYCOCHOLIC ACID IN PATIENTS WITH LIVER DISEASE.

(Eng.) Sewell, R. B.; Hoffman, N. E.; Ireton, H. J. C.; Smallwood, R. A. (Austin Hosp., Heidelberg, Victoria 3084, Australia). *Aust. N.Z. J. Med.* 7(2):148-150; 1977.

The diagnostic value of determining the plasma disappearance of i.v. injected radiolabeled glycocholic acid (5 μCi) in liver disease was studied in 10 patients with liver cell necrosis (chronic active hepatitis, alcoholic hepatitis, liver cirrhosis, cholestasis, and liver carcinoma), 10 patients with diffuse hepatocellular disease without liver cell necrosis (alcoholic liver disease), and 3 patients without diffuse hepatocellular disease. The retention of radiolabel in the plasma was similar in the patients with hepatocellular disease and in those without it. The label retention in the patients with liver cell necrosis (8.90 ± 2.46, 7.20 ± 2.98, 4.91 ± 3.10, 3.92 ± 2.92, and 3.44 ± 2.69% at 4, 6, 10, 15, and 20 min, resp.) was significantly higher than that in those with liver disease but without necrosis (6.18 ± 1.68, 4.21 ± 1.45, 2.34 ± 0.97, 1.46 ± 0.90, and 0.99 ± 0.69%, resp.; $p<0.01$, $p<0.01$, $p<0.025$, $p<0.025$, and $p<0.025$, resp.). Comparison of the retention in the patients with liver disease but without necrosis with previous data from normal subjects showed that the two groups are indistinguishable. This test is not a sensitive index of the presence of significant liver disease.

7093 SERUM LIPOPEROXIDE LEVEL IN PATIENTS SUFFERING FROM LIVER DISEASES.

(Eng.) Suematsu, T.; Kamada, T.; Abe, H.; Kikuchi, S.; Yagi, K. (Osaka Univ. Medical Sch., Osaka 553, Japan). *Clin. Chim. Acta* 79(1):267-270; 1977.

A micro-method was used to determine the serum lipoperoxide levels in 14 patients with acute hepatitis, 8 patients with fulminant hepatitis, 16 patients with chronic active hepatitis, 39 patients with compensated liver cirrhosis, 4 patients with decompensated liver cirrhosis, 11 patients with fatty liver, and 121 healthy subjects. The mean serum lipoperoxide level in the healthy subjects was 1.77 ± 0.36 nmol/0.5 ml serum, and the level seldom exceeded 2.0 nmol/0.5 ml serum. The mean levels were significantly elevated in all patients with liver disease. The levels were 3.20 ± 0.88, 6.55 ± 0.88, 3.73 ±

1.83, 1.96 ± 0.65, 4.11 ± 0.53, and 3.80 ± 0.79 nmol/0.5 ml serum in acute hepatitis ($p<0.001$), fulminant hepatitis ($p<0.001$), chronic active hepatitis ($p<0.001$), compensated liver cirrhosis ($p<0.025$), decompensated liver cirrhosis ($p<0.001$), and fatty liver ($p<0.001$), resp. Because other studies have indicated that increased serum lipoperoxide levels may cause degeneration of the endothelial walls of vessels in some organs, the large increases in lipoperoxide levels seen in these diseases may be responsible for secondary disorders in organs other than the liver.

7094 HEPATIC SCINTIGRAPHY IN MANAGEMENT OF INFANTS AND CHILDREN WITH LIVER DISEASE.

(Eng.) Smith, A. L.; Mowat, A. P.; Williams, R. (King's Coll. Hosp. Medical Sch., Denmark Hill, London SE5 8RX, England). *Arch. Dis. Child.* 52(8): 633-637; 1977.

Scintiscans of the liver and spleen using ^{99m}Tc sulfur colloid in 15 infants with extrahepatic biliary atresia and 11 infants with severe obstructive jaundice (7 with genetic deficiency of α_1-antitrypsin) showed similar liver size, pattern of isotope uptake, and splenic abnormality, with no distinguishing features. In 37 older children with various liver disorders (8 chronic active hepatitis, 8 cirrhosis, 3 cystic fibrosis with hepatosplenomegaly and abnormal liver function tests, 2 congenital hepatic fibrosis, 2 glycogen storage disease, 9 extrahepatic portal hypertension, and 5 space-occupying defects in the liver), there was a tendency for patients in each pathological group to show a particular pattern of uptake by the liver and spleen, such as reduced liver size, peak count rate, and enlarged spleen in cirrhosis. However, there was considerable overlap among these groups. The main value of the scan in older children was in excluding or showing space-occupying lesions of >2 cm in diameter in those presenting with hepatomegaly of uncertain cause. In all five children with space-occupying lesions, the scan showed an area of defective uptake. On selenomethionine scanning, the isotope was taken up by the filling defect in each of two patients with hepatoblastoma and in an infant with hemangioendothelioma. However, selenomethionine was not taken up by a patient with rhabdomyosarcoma and one with a hydatid cyst. An important new observation concerning the hepatic tumor patients was that the cold area on the ^{99m}Tc scan that takes up selenomethionine (^{75}Se) cannot necessarily be interpreted as primary liver cell cancer, since the hemangioendothelioma behaved similarly. In children with chronic liver disease, the main value of the scan is in confirming the presence of liver disease when the biochemical and clinical findings are equivocal. Liver scanning is concluded to have no place at present in the management of infants with obstructive jaundice.

7095 CLINICAL ASPECTS AND DIAGNOSIS OF BUDD-CHIARI SYNDROME.

(Ger.) Zimmerman, H. B.; Schimmelpfennig, W.; Wack, R. (II. Medizinische Klinik des Bereichs Medizin, Humboldt-Universitat, Schumannstrasse 20/21, DDR-104 Berlin, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 36 (3/4):159-161; 1976.

General etiological, diagnostic, and therapeutic aspects of Budd-Chiari syndrome are reviewed, and six new cases (5 women, 1 man, aged 19-41 yr) are reported. Two of the women had been using oral contraceptives. The length of the prodromal symptoms was 1-12 months. The symptoms included epigastric pain (3 patients), ascites (6), edema (5), hepatomegaly (6), splenomegaly (3), and polycythemia (1). The bilirubin level was 0.9-4.1 mg/100 ml, the alkaline phosphatase level was 29-330 U/l, and the glutamic-pyruvic transaminase level was 12-100 U/l. Liver cirrhosis was found in two patients and portal hypertension in five. Thrombosis of the hepatic vein or pelvic veins was found in all six. Exploratory laparotomy was performed in two patients, reconstruction of the hepatic vein in one, and cervical lymphovenous anastomosis in one. Two patients did not undergo surgery. Surgery was successful only in the 41-yr-old man who underwent cervical lymphovenous anastomosis; he was cured in 8 months, but the three other patients died within 2-17 months.

7096 SIGNIFICANCE OF α-FETOPROTEIN (AFP) IN LIVER TUMORS (HEPATOBLASTOMA AND HEPATOMA) IN CHILDREN.

(Fre.) Hata, Y.; Uchino, J.; Kasai, Y.; Nishi, S. (First Dept. Surgery, Hokkaido Univ., Sapporo, Japan). *Ann. Chir. Infant.* 18(1):73-77; 1977.

A simple radial immunodiffusion method can be used to measure α-fetoprotein (AFP) levels in children with hepatoblastomas and hepatomas. In one patient, a 13-yr-old boy, preoperative AFP levels were 52 mg/dl (normal, <10 mg/dl). By 4 weeks postsurgery (PS), AFP was 0-1 mg/dl; however, the child became AFP positive again 2 months PS. The tumor recurrence was not detected by hepatic scintigraphy until 4 months PS and by liver function tests until 6 months PS. AFP levels were temporarily depressed during chemotherapy, but they rose again when tumor growth resumed. These results indicate that measurements of AFP levels may be valuable in the early and accurate detection of liver tumors or recurrences in children.

7097 DIAGNOSTIC EVALUATION OF SERUM LIPIDS IN PATIENTS WITH HEPATOCELLULAR CARCINOMA.

(Eng.) Yoshida, T.; Okazaki, N.; Yoshino, M; Araki, E. (Natl. Cancer Center Hosp., 1-1, Tsukiji 5-chome, Chuo-ku, Tokyo 104, Japan). *Jpn. J. Clin. Oncol.* 7(1):15-20; 1977.

Serum lipid levels were determined in 24 patients with hepatocellular carcinoma (18 of whom also had liver cirrhosis), 13 patients with liver cirrhosis only, and 18 healthy subjects after an overnight fast. There was no significant difference among the three groups in terms of the average level of serum total lipids. However, patients with hepatocellular carcinoma showed levels of serum total cholesterol (221.3 ± 81.2 mg/100 ml, $p<0.005$), esterified cholesterol (133.3 ± 55.3 mg/100 ml, $p<$

0.05), and phospholipid (239.9 ± 90.9 mg/100 ml, $p<0.025$) that were significantly elevated compared with those of patients with cirrhosis only (145.9 ± 52.5, 92.5 ± 32.8, and 160.8 ± 69.4 mg/100 ml, resp.). Patients with hepatocellular carcinoma plus liver cirrhosis showed significant elevations in levels of total cholesterol (212.3 ± 73.5 mg/100 ml, $p<0.01$) and phospholipid (233 ± 90.6 mg/100 ml, $p<0.05$) compared with those in patients with cirrhosis only. Patients with hepatocellular carcinoma without liver cirrhosis showed significant elevations in total cholesterol (244.3 ± 100.9 mg/100 ml, $p<0.01$), esterified cholesterol (170.0 ± 70.0 mg/100 ml, $p<0.01$), and phospholipid (255.0 ± 98.4 mg/100 ml, $p<0.05$) compared with levels in patients with cirrhosis only. Determination of serum lipids is concluded to be useful in differentiating hepatocellular carcinoma from liver cirrhosis. It may also be useful in diagnosing the development of hepatocellular carcinoma during the course of liver cirrhosis.

7098 SURGICAL TREATMENT OF PRIMARY LIVER CARCINOMA. (Eng.) Flatmark, A.; Fretheim, B.; Knutrud, O. (Rikshospitalet, Oslo, Norway). *Chir. Gastroenterol.* 11(1):129-131; 1977.

Experience with 44 patients (including 13 children) surgically treated for liver carcinoma was reviewed. Liver cirrhosis was diagnosed in three adult patients. General weakness and epigastic pain were the most common presenting symptoms. Only two patients were icteric, and a 17-yr-old girl presented with acute intraperitoneal bleeding due to rupture of the tumor. Selective angiography and liver venography were performed preoperatively in all patients. Twenty-one patients were screened for alpha-fetoprotein, with a positive result in only one child. Laparotomy was performed in all patients, and resectability was 36%. Extended right lobectomy was carried out in five patients, and the right or left hepatic lobe was removed in three and eight patients. There was one postoperative death, and this was caused by bleeding from a hepatic vein. Nine patients are alive 1-8.5 yr after liver resection. The longest survivor has recurrence of the liver tumor with metastasis. Two patients died of myocardial infarction 7.5 and 4 yr, resp., after surgery. Four patients died of matastasis, three within 1 yr and one within 2 yr after surgery; the 1-yr survival rate was 75%. The results favor radical surgery in primary liver carcinoma when the tumor is operable.

7099 QUADRUPLE CHEMOTHERAPY VERSUS RADIOTHERAPY IN TREATMENT OF PRIMARY HEPATOCELLULAR CARCINOMA. (Eng.) Cochrane, A. M. G.; Murray-Lyon, I. M.; Brinkley, D. M.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5, England). *Cancer* 40(2):609-614; 1977.

A controlled trial of chemotherapy alone versus radiotherapy followed by chemotherapy for the treatment of 18 patients with primary hepatoma is reported. All patients received chemotherapy, which consisted of 500 mg 5-fluorouracil, 500 mg cyclophosphamide, 50 mg methotrexate, and 2 mg vincristine given systematically once every 3 weeks as single bolus injections. In eight patients, a course of radiotherapy was completed 2 months before the start of chemotherapy, with a total dose of 3,000 rads being delivered in 15 fractions over 21 days. Patients receiving chemotherapy alone survived considerably longer (median, 21.0 weeks; range, 4-72 weeks) than did those receiving radiotherapy/chemotherapy (median, 12 weeks; range, 2-28 weeks). Length of survival in both treatment groups was related to age, length of history, levels of serum bilirubin and aspartate transaminase, and the presence of cirrhosis or ascites. When patients were subdivided according to these criteria into those with less severe disease (grade A) and those with severe disease (grade B), grade A patients had a median survival of 54 weeks after treatment with chemotherapy alone compared with 24 weeks after treatment with radiotherapy/chemotherapy. This difference in survival just failed to reach statistical significance ($p<0.07$). However, survival of patients with grade B disease was equally poor in both treatment groups, being 5 weeks for the chemotherapy group and 7.5 weeks for the chemotherapy/radiotherapy group. Quadruple chemotherapy alone is concluded to be a valuable form of therapy for grade A patients, whereas neither form of therapy appears to be of any benefit to grade B patients.

7100 THE INDUCTION OF LIVER CELL CANCER BY CHEMICALS. (Eng.) Wogan, G. N. *In: Liver Cell Cancer*. Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Co.): pp. 121-152; 1976.

Chemicals that induce liver cancer in experimental animals and are encountered by humans as components of the general environment are reviewed. Of the chemicals known to be hepatocarcinogenic to experimental animals, the strongest evidence of involvement in human liver cancer exists for the aflatoxins. Studies of various human populations have shown a positive association between aflatoxin ingestion and liver cancer incidence. Other experimental hepatocarcinogens that may be involved in human liver cancer include: sterigmatocystin and, possibly, other mycotoxins; certain pyrrolizidine alkaloids; cycasin and related glycosides; and carcinogenic nitrosamines or nitrosamides formed through the interaction of nitrite and nitrosatable substances in the environment. It is impossible to assess the importance of other known synthetic carcinogens, such as chlorinated hydrocarbons, even though some of them are widely distributed in the environment. Although humans are exposed to trace amounts of chlorinated hydrocarbons such as carbon tetrachloride and chloroform in municipal drinking water, there is no epidemiologic evidence that they cause human liver cancer.

7101 PRIMARY CARCINOMA OF THE LIVER: A HISTOLOGICAL STUDY OF 27 CASES OF PRIMARY CAR-

CINOMA OF THE LIVER FROM MALAWI. (Eng.) Norredam, K. (Esperance Alle 9, 2920 Charlottenlund, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*]. 85(4):461-469; 1977.

Liver biopsies from 27 Bantu patients from Malawi with primary carcinoma of the liver were examined histologically. All of the biopsies showed hepatocellular carcinoma. Structurally, the tumors consisted of trabeculae, singly or in groups, separated by a variable amount of connective tissue that in three cases was so pronounced the tumor had a scirrhous appearance. A characteristic feature of the tumor tissue was the scarcity of reticulin inside the trabeculae, in contrast to the elaborate reticulin network of benign liver tissue. Using a reticulin staining technique, the cytoplasm and, especially, the nuclei of the malignant cells were markedly stained, but the benign liver cells were left unstained. In the 26 cases in which the grade of tumor differentiation could be evaluated, there were 3 grade I tumors, 10 grade II, 5 grade III, and 8 grade IV. Reticulin staining was not useful in evaluating the degree of tumor differentiation. Among 15 evaluable patients, 12 had postnecrotic-type cirrhosis.

7102 CARCINOID TUMORS WITH HEPATIC METASTASES. ANATOMOCLINICAL AND THERAPEUTIC ASPECTS. (Fre.) Saubier, E. C.; Gerdil, F.; Partensky, C.; Barbe, C.; Mallet-Guy, Y. (Hopital Ed.-Herriot, 69374 Lyon Cedex 2, France). *Lyon Chir.* 73(2): 132-140; 1977.

The treatment of seven patients with hepatic metastases from carcinoid tumors is reported. Hepatomegaly was present in four. The carcinoid syndrome was primary in two patients with obvious flushing, secondary in two others, and doubtful in one. The tumor was situated in the ileum in three patients, on the right lower lobar branch in one, and in the sigmoid in one; it could not be located in two patients, even at autopsy. Multiple small tumors occurred in two patients with ileal tumors, which made radiological diagnosis difficult. Of the three ileal tumor patients, small intestinal transit was positive in one, negative in another, and normal in the third. The results were confirmed by mesenteric arteriography. Diffuse mesenteric scleroses affecting the peritoneal serosa, arteries, veins, and lymphatics were found in these three patients. Hepatic metastases in all seven patients were detected by palpation, laparoscopy, hepatic scintigraphy, and celiac arteriography. A high level of 5-hydroxyindoleacetic acid (5-HIA) was found in the two patients with primary carcinoid syndrome and in one with secondary syndrome; 5-HIA was normal in two patients. Hepatic metastases were removed by repeat operations in four patients, one of whom required three interventions. All surgical procedures were enucleoresections; in one patient, the procedure was associated with a planned left lobectomy. One 72-yr-old woman died postoperatively of profuse hemorrhaging. Autopsy showed a blood-filled small intestine. The other three patients who underwent surgery survived 7 yr and 20 and 37 months, resp. Of the three nonoperated patients, one died of respiratory and renal insufficiency 25 months after the beginning of symptoms and one died of carcinoid tumor after 10 months. One is alive with metastases and a high 5-HIA level (27 mg/24 hr), but this patient did not have a carcinoid syndrome at the time.

7103 HEPATIC NEUROBLASTOMA. (Fre.) Uchino, J.; Hata, Y.; Kasai, Y.; Kikuchi, K. (First Dept. Surgery, Hokkaido Univ., Sapporo, Japan). *Ann. Chir. Infant.* 18(1):65-73; 1977.

Neuroblastomas were diagnosed in 3/13 children with malignant liver tumors. Laparotomies revealed greatly enlarged livers with diffuse tumors that had few necrotic or hemorrhagic areas on their surfaces. The catecholamine granules found by electron microscopy and the high serum levels of catecholamine metabolic products were characteristic of neuroblastomas. However, the α-fetoprotein levels were normal for children in this age range (12 days-3 months). The tumors were treated with radio- and/or chemotherapy, and the patients were well 2, 7, and 12 yr later, indicating a more optimistic prognosis for these tumors than for hepatoblastomas.

7104 TRUE HEPATIC TERATOMA WITH HIGH ALPHA FETOPROTEIN IN SERUM. (Eng.) Todani, T.; Tabuchi, K.; Watanabe, Y.; Tsutsumi, A. (Okayama Univ. Medical Sch., 2-5 Shikatzcho, Okayama City, Japan). *J. Pediatr. Surg.* 12(4):591-592; 1977.

The case of a 4-month-old girl with a true hepatic teratoma, producing a high level of alpha fetoprotein, is presented. Preoperatively, the serum alpha fetoprotein level was 2.5 mg/dl. The well-encapsulated tumor, measuring 12 x 12 x 10 cm, was located at the parietal surface of the quadrate lobe. After its removal, repeated alpha fetoprotein tests were negative. Histologically, the tumor had the features of a true malignant teratoma, with three germinal layers. The patient is asymptomatic at 2 yr of age. This case suggests that a hepatic teratoma, regardless of malignancy, is also a tumor that produces alpha fetoprotein.

7105 BILE ACIDS IN SERUM AND BILE OF INFANTS WITH CHOLESTATIC SYNDROMES. (Eng.) Deleze, G.; Paumgartner, G. (Dept. Clinical Pharmacology, Univ. Berne, Murtenstrasse 35, CH-3010 Berne, Switzerland). *Helv. Paediatr. Acta* 32(1):29-38; 1977.

Serum bile acids were measured in 18 neonates and infants with various cholestatic conditions. The concentration of total bile acids was markedly elevated (32-336 μM) in all patients studied. The cholate (C)/chenodeoxycholate (CDC) ratio in serum was <1 in each of eight patients with neonatal hepatitis syndrome (range, 0.31-0.80) and in each of two patients with extrahepatic biliary atresia (0.46 and 0.58). The C/CDC ratio was >1 in each of two patients with chronic intrahepatic cholestasis (1.60 and 1.94). Among six patients with posthemolytic cholestasis, the C/CDC ratio was >1 in two cases (1.99 and 2.23) and <1 in four cases (range, 0.28-0.82). The administration of cholestyramine (4 g/day) to an infant with neonatal hepatitis of unknown etiology decreased the total bile acid concentration markedly (from almost 300 to <75 µM) and increased the C/CDC ratio (from 0.4 to 1.6). A similar effect was observed in three other patients with patent extrahepatic bile ducts. Thus, cholestyramine administration may be of diagnostic value for the evaluation of bile duct patency in infant cholestasis. A comparison of the bile acid pattern in the serum and bile of three patients with cholestatic syndromes revealed that the C/CDC ratio was always higher in bile than in serum (0.71 versus 0.59 and 1.35 versus 0.31 for two cases of neonatal hepatitis syndrome of unknown etiology, and 1.24 versus 0.51 for a case of posthemolytic cholestasis). 3β-Hydroxy-5-cholenoic acid was found in serum, but not in bile. This finding suggests that impairment of biliary excretion rather than increased hepatic synthesis is responsible for the elevation of this monohydroxy bile acid in serum.

7106 POSTOPERATIVE INTRAHEPATIC CHOLESTASIS.

(Eng.) Hampel, N.; Lichtig, C.; Gersh, I.; Gellei, B. (Rambam Univ. Hosp., Technion Sch. Medicine, Haifa, Israel). *Int. Surg.* 62(1):51-54; 1977.

The diagnostic problems, pathophysiology, and treatment of postoperative intrahepatic cholestasis are illustrated by four cases. The patients included a 70-yr-old man, a 65-yr-old man, a 58-yr-old man, and a 57-yr-old woman who underwent surgery for pharyngolaryngoesophagectomy with colon replacement of the esophagus, for prostatectomy, gastric malignancy, and for the creation of an aortobifemoral bypass graft, resp. Hypotension occurred during surgery in cases 1, 3, and 4. The remaining patient was admitted in shock (related to hematemesis and melena) 24 days after the operation. In the four cases, the maximum bilirubin levels were 11.5-32.0 mg/100 ml, and more than half of it was conjugated. In case 1, the SGOT rose to 300 U, and histological examination revealed prominent centrilobular necrosis without any signs of hepatitis. SGOT levels in the other three patients were moderately increased, and two of these showed centrilobular necrosis. Sepsis, leading to a proposed disruption of the secretory mechanism of conjugated bilirubin, may have been a factor in the development of jaundice in cases 1 and 2. Three patients died, but death was not due to postoperative jaundice. The second patient died 2 days after an exploratory operation for obstructive jaundice. This case emphasizes the importance of recognizing the syndrome as a functional disorder that must not be treated by surgery.

7107 EEG FINDINGS IN HEPATIC ENCEPHALOPATHY DURING MODERN CONSERVATIVE TREATMENT.

(Ger.) Gemende, G.; Gemende, I. (Chirurgische Klinik, Ernst-Moritz-Arndt-Universitat, Friedrich-Loeffler-Strasse 23b, DDR-22 Greifswald, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 36(3/4):183-185; 1976.

Regular EEG examinations are recommended for patients with hepatoportal encephalopathy, both for the progressive forms (hepatic coma) and during the initial stages of long-standing obstructive jaundice or compensated liver cirrhosis. During the acute phase, certain bioelectric phenomena are indicative of the degree of brain stem dysfunction. Changes in the intensity and frequency of the biorhythms parallel cerebral decompensation and recompensation and are indirect criteria of the metabolic disorders. Without being a diagnostic tool, the EEG characterizes the current functional status of the brain during therapy.

7108 BLOOD CELL GLYCOGEN SYNTHETASE ACTIVITIES IN HEPATIC GLYCOGEN SYNTHETASE DEFICIENCY.

(Eng.) Gitzelmann, R.; Aynsley-Green, A.; Williamson, D. H. (Univ. Zurich, Kinderspital, 8032 Zurich, Switzerland). *Clin. Chim. Acta* 79(1):219-221; 1977.

The use of RBC and WBC in the diagnosis of hepatic glycogen synthetase deficieny was studied in a patient with glycogen synthetase deficiency, three members of her family, and in healthy adults. The mean glycogen synthetase activities in the RBC and WBC of healthy controls were 53.4 ± 13.0 mU/g hemoglobin and 2.3 ± 0.6 U/g protein, resp. The levels were normal in the RBC and WBC of both the patient and the family members; they ranged between 2.4 and 4.1 U/g protein in the WBC, and the levels in the RBC of the patient and her brother were 68.2 and 82.5 mU/g hemoglobin, resp. The brother was found to have glycogen synthetase deficiency, although to a lesser degree than that of his sister. The presence of active enzyme in RBC as well as WBC in both children is strong evidence for the existence of genetically different forms of glycogen synthetase. Since this study shows that glycogen synthetase of the blood cells is not representative for the liver enzyme, hepatic glycogen synthetase deficiency cannot be diagnosed by enzyme assay performed on blood cells.

7109 CONTROL OF HEPATIC BLEEDING WITH MICROFIBRILLAR COLLAGEN.

(Eng.) Morgenstern, L.; Michel, S. L.; Austin, E. (Cedars-Sinai Medical Center, P. O. Box 48750, Los Angeles, CA 90048). *Arch. Surg.* 112(8):941-943; 1977.

Thirty-six cases in which intractable bleeding from the liver surface was treated with microfibrillar collagen are reported. Microfibrillar collagen was effective in all of 13 patients with bleeding from the gallbladder bed, in 6 of 7 patients with parenchymal lacerations, in all 5 patients with bleeding at a liver biopsy site, in both patients with capsular denudation, in both patients with hemangiomas, and in all 3 patients with bleeding after hepatic resection. Microfibrillar collagen, alone or in combination with other hemostatic measures, was also successful in the treatment of spontaneous rupture of a hepatoma in a cirrhotic liver; removal of a large solitary, metastatic, myxoid liposarcomatous mass from the dome of the right lobe; bleeding from the wall of a liver abscess after evacuation of the purulent material within it; and evacuation and biopsy of a cyst high on the dome of the right lobe. The use of microfibrillar collagen was considered to be lifesaving in at least six cases. The patient in which this treatment failed bled from a deep wound presumably caused by a retractor during a Whipple procedure. In this case, bleeding continued into the hepatic parenchyma. This case demonstrated that microfibrillar collagen should not be applied to deep hepatic lacerations where only a portion of the laceration can be effectively packed. The authors believe that microfibrillar collagen is superior to topical hemostatic agents such as oxidized cellulose or gelatin foam, inasmuch as it has a more physiologic basis for action (activation of platelet clotting factors), it adheres well to moist surfaces, and it is well tolerated even in the presence of severe infection.

7110 THERAPY OF HEMOSTATIC DISTURBANCES IN LIVER DISEASES: PROTHROMBIN COMPLEX CONCENTRATES.

(Ger.) Fischer, M. (Krankenhaus der Stadt Wien-Lainz, Wolkersbergenstrasse 1, A-1130 Vienna XIII, Austria). *Z. Gastroenterol.* 14(6):650-653; 1976.

The indications, dosage, effect, and possible risks of prothrombin complex concentrate therapy for patients with hemostatic disorders due to liver diseases are reviewed. Administration of prothrombin complex or partial prothrombin complex concentrates is indicated in liver diseases such as hepatitis, liver cirrhosis, liver necrosis, and esophageal varices associated with at least 20% factor II, VII, IX, and X deficiency. The dosage is basically determined by clotting test results. The initial dose should be 15-20 U/kg, then 5-15 U/kg at 6- to 12-hr intervals. Low-dose heparinization (30-40 IU/kg s.c. at 6- to 12-hr intervals) is recommended to prevent disseminated intravascular coagulopathy. Transmission of hepatitis B and the induction of intravascular coagulation are the major hazards involved in prothrombin complex therapy.

7111 APLASTIC ANEMIA ASSOCIATED WITH SUBMASSIVE HEPATIC NECROSIS: REPORT OF FOUR CASES.

(Eng.) Watananukul, P.; Israsena, S.; Dechakaisaya, S. (Chulalongkorn Hosp. and Medical Sch., Rama 4th Rd., Saladang, Bangkok, Thailand). *Arch. Intern. Med.* 137(7):898-901; 1977.

The cases of four patients (men, aged 20-33 yr) with fatal aplastic anemia associated with submassive hepatic necrosis are presented. The first patient presented with fever, jaundice, and hepatomegaly after having taken phenacetin and phenylbutazone. Pancytopenia developed 8 weeks after the onset of hepatitis. The liver disease was still progressive when the patient died with respiratory tract infection. Submassive hepatic necrosis and aplastic bone marrow were seen at necropsy. The bone marrow depression from phenacetin and phenylbutazone cannot be excluded. The second patient had recurrent episodes of hepatitis. Pancytopenia developed, and the liver biopsy specimen was consistent with relapsing hepatitis. Both hepatitis and aplastic anemia showed little improvement after blood transfusion, prednisone, and antibiotic therapy. The patient died of lobar pneumonia. Aplastic anemia was diagnosed in the third patient during the course of acute hepatitis. The patient died of septicemia, and at autopsy the liver showed submassive hepatic necrosis. In the fourth patient, three relapses of hepatitis occurred shortly after his recovery from an attack of acute viral hepatitis. Pancytopenia developed during the last relapse. No adequate explanation for the association between hepatic necrosis and aplastic anemia is available, but infectious hepatitis should be accepted as a potential cause of aplastic anemia. Phagocytic cells were observed in the bone marrow during the time of relapse in patient 4 and gradually decreased after he became asymptomatic. The nuclei of these cells were pushed against the cell membrane, while the cytoplasm was filled with one or more platelets, WBC, and RBC precursors. The phagocytosis of platelets and myeloid and erythroid cells may be one of the immunological mechanisms against the patient's own blood cells, and may have been an essential mechanism leading to aplastic anemia.

7112 NODULAR TRANSFORMATION OF THE LIVER: REPORT OF A CASE.

(Eng.) Connolly, C. E.; O'Brien, M. J. (Galway Medical Sch., Galway, Ireland). *Hum. Pathol.* 8(3):350-352; 1977.

The rare case of a patient with portal hypertension due to nodular transformation of the liver is presented. The patient presented with abdominal distention, dysphagia, ascites, and splenomegaly. Esophagoscopy revealed a tight postcricoid stricture, and a barium swallow demonstrated gross esophageal varices. A liver scan showed diffuse irregular uptake suggestive of cirrhosis. Liver biopsies on two occasions were reported as normal. The patient died after massive hematemesis due to bleeding esophageal varices. At autopsy, the liver weighed 1,265 g and was smaller than normal, but the external surface was smooth and showed no evidence of cirrhosis. Portal vein thrombosis was present. Serial sectioning of the liver revealed multiple 1- to 2-cm tan or pale nodules situated both in the hilum and in the periphery of both lobes. The liver in this case differed from the cirrhotic liver in one essential respect; although nodules that were probably regenerative in nature were present, as in cirrhosis, there were no delimiting scars or fibrous bands. Because of the apparently normal liver architecture in a small biopsy specimen, the diagnosis of this condition by needle biopsy is extremely difficult; nodular transformation of the liver should be suspected in patients with evidence of portal hypertension and normal liver biopsies.

7113 PYLORODUODENAL DEFORMITY DUE TO LIVER MALFORMATION ASSOCIATED WITH OMPHALOCELE.

(Eng.) Oh, K. S.; Strife, J. L.; Fischer, K. C.; Teele, R. (Children's Hosp. Pittsburgh, 125 De Soto St., Pittsburgh, PA 15213). *Am. J. Roentgenol.* 128(6):957-960; 1977.

The cases of three infants in whom a malpositioned, malformed liver caused pyloroduodenal deformity and apparent pyloric obstruction are reported. In all cases, vomiting occurred after surgical repair of an omphalocele; in one case, the vomiting did not occur until the patient was 1 yr old. The radiographic characteristics in the three patients included a soft tissue mass in the middle and anterior portion of the abdomen, external compression of the pylorus, and malrotation of the midgut. The compression was distinguished from hypertrophic pyloric stenosis by the lack of a symmetric pyloric narrowing, lack of significant elongation of the pyloric channel, and absence of a "shoulder sign." In the patient in whom the onset of vomiting was delayed, liver-spleen isotope scans and ultrasonographic scans demonstrated the malformed and malpositioned liver when the patient was 10 yr old. The cause of recurrent vomiting and abdominal pain in this patient was uncertain, but there was evidence of external compression of the pylorus by the pedicle of the accessory lobe of the malformed liver. In another patient, the relief of vomiting by a gastrojejunostomy suggested that the accessory lobe of the malformed liver might have been the cause. In the remaining patient, adhesion may have contributed to the symptoms, in addition to pyloric compression by the malformed and malpositioned liver. In infants with omphaloceles, the surgeon should evaluate the size, shape, position, and relationship of the liver to the stomach at the time of initial surgery. A bypass operation such as gastrojejunostomy may be considered if pyloric compression by the malformed liver is found.

7114 THE NEUROLOGICAL MANIFESTATIONS OF PORPHYRIA: A REVIEW.

(Eng.) Becker, D. M.; Kramer, S. (Sch. Pathology, Univ. Witwatersrand, Johannesburg, South Africa). *Medicine (Baltimore)* 56(5):411-423; 1977.

Three hereditary hepatic porphyrias, acute intermittent porphyria, porphyria variegata, and hereditary coproporphyria, are reviewed in terms of their biochemical and clinical manifestations, pathogenesis, and treatment. They are characterized biochemically by increased excretion of porphyrins and the porphyrin precursors δ-aminolevulinic acid (ALA) and porphobilinogen (PBG) and clinically by episodes of acute neurological involvement. The symptoms and signs of acute attacks from all three porphyrias are, in decreasing frequency: abdominal pain, constipation, vomiting, vesical symptoms, tachycardia, hypertension, paresthesias, and weakness with ascending paralysis, which may progress to quadriplegia and respiratory failure. The increased production of porphyrins and porphyrin precursors in these porphyrias has been shown to be due to partial enzyme blocks along the heme biosynthetic pathway that result in secondary depression of the key enzyme ALA synthetase. Therefore, the neurological manifestations could be related to a decrease in essential heme-proteins or other heme-containing compounds within the nervous system or to a toxic effect of the overproduction of ALA and PBG. Porphyrin precursors have been shown to have potent pharmacological effects on the nervous system, and these are possibly related to the γ-aminobutyric acid receptor and binding site-porphyrin precursor interactions. Current studies on therapy for acute attacks of porphyria are concentrating on the suppression of ALA synthetase activity and, consequently, on reduced ALA and PBG production. Several of these therapeutic methods have met with remarkable success.

7115 HEPATOCYTE GIANT MITOCHONDRIA: AN ALMOST CONSTANT LESION IN SYSTEMIC SCLERODERMA.

(Eng.) Feldmann, G.; Maurice, M.; Husson, J. M.; Fiessinger, J. N.; Camilleri, J. P.; Benhamou, J. P.; Housset, E. (Hopital Beaujon, F-92118 Clichy, France). *Virchows Arch.* [*Pathol. Anat.*] 374(3):215-227; 1977.

Electron microscopic studies of the liver were performed in 14 women with systemic scleroderma but with no clinical manifestation of liver disorder. Histologically, the liver was normal in 10 patients. Steatosis was present in 1 patient, portal sclerosis in 2, and cloudy swelling of some hepatocytes in 2. In 13 patients, giant mitochondria with a diameter ≥5 μm were observed in the hepatocytes. In 11 of these patients, giant mitochondria were present in about 20% of the hepatocytes; they were less frequent in the 2 remaining patients. The structure of the giant mitochondria was markedly abnormal, especially the arrangement of the cristae. Instead of being perpendicular to the inner mitochondrial membrane, as they are in normal hepatocyte mitochondria, the cristae were either parallel to the inner membrane or randomly distributed throughout the matrix. The matrix of some mitochondria contained paracrystalline inclusions (in the neighborhood of the cristae) or tubular linear structures with a diameter of 40 nm. In general, the paracrystalline inclusions were absent when the tubular structures were present. The other organelles of the hepatocytes were normal. No mitochondrial abnormalities were observed in the biliary cells, endothelial cells, Kupffer cells, lipocytes, or fibroblasts. The mechanism of formation of giant mitochondria in systemic scleroderma is unknown.

7116 PROGRESS IN LIVER TRANSPLANTATION.

(Eng.) Putnam, C. W.; Halgrimson, C. G.; Koep, L.; Starzl, T. E. (Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80262). *World J. Surg.* 1(2):165-175; 1977.

Experience with 114 patients who underwent liver transplantation is reported. The overall 1-yr survival rate was 29%, with the longest survivor living 6 yr, 8 months post-transplantation. Most of the early deaths were caused by technical complications, frequently related to difficulties in establishing and maintaining adequate biliary drainage. More recent deaths are attributed to a variety of reasons, including recurrent tumor, hepatitis, bile duct obstruction, and chronic rejection. Favorable indications for liver transplantation include biliary atresia, chronic aggressive hepatitis, inborn errors of metabolism, and certain other benign hepatic diseases such as primary biliary cirrhosis and the Budd-Chiari syndrome. Alcoholic cirrhosis is a less favorable indication, and primary hepatic malignancy is a relative contraindication. The immunologic criteria for donor-recipient selection are much less rigid than those for renal transplantation. Biliary reconstruction is the principal technical problem encountered with orthotopic liver transplantation. Although no one technique of biliary reconstruction is satisfactory for all patients, the following principles have emerged: use of the cystic duct, with its inherently high risk of obstruction should be avoided; the liver should be protected from the bacterially contaminated gastrointestinal contents by a defunctionalized Roux-en-Y limb of jejunum or by the sphincter of Oddi; radiographic visualization of the biliary tree, either by tube cholangiography or by the transhepatic approach, must be performed whenever jaundice reappears after transplantation; and if obstruction is detected, prompt reoperation is vital.

7117 CURRENT STATUS OF LIVER TRANSPLANTATION. EXPERIENCE WITH 50 PERSONAL CASES OF LIVER TRANSPLANTATION. IMPROVEMENT OF EARLY POSTOPERATIVE SURVIVAL BY A NEW BILE DUCT DRAINAGE TECHNIQUE. (Ger.) Calne, R. Y.; Williams, R. (Addenbrooke's Hosp., Hills Rd., Cambridge CB2 200, England). *Internist (Berlin)* 17(12):597-603; 1976.

Experience with 50 liver transplantations performed since May 1968 is presented. Liver transplantation is indicated for patients with liver cirrhosis, bile duct atresia, primary liver cancer, portacaval anastomosis, and poorly controllable portacaval encephalopathy who would not benefit from any other therapy. Heterotopic auxiliary liver transplantation was performed four times, but orthotopic transplantation is more efficient because of the better vascularization it provides. The last 10 transplant patients were supplied with improved biliary drainage by use of the donor's gallbladder as a pedicle graft conduit between the donor's and recipient's bile ducts. As a result, the sphincter of Oddi is preserved and reflux cholangitis is prevented. Although the liver is rejected much less frequently than the kidney, immunosuppressive treatment with azathioprine or cyclophosphamide and steroids is necessary, even though two patients fared rather well without steroids. Nineteen patients died within 1 month of transplantation, 15 within 1-6 months, 4 within 6-12 months, and 2 died at 25 and 63 months post-transplantation, resp. Ten patients operated since February 1974 are alive.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

7133 BENIGN COURSE OF EXTREME HYPERBILIRUBINEMIA IN SICKLE CELL ANEMIA: ANALYSIS OF SIX CASES. (Eng.) Buchanan, G. R.; Glader, B. E. (Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX 75235). *J. Pediatr.* 91(1):21-24; 1977.

The approach to the management and outcome of extreme hyperbilirubinemia in patients with sickle cell anemia was defined by reviewing experience with marked hyperbilirubinemia in six children with sickle cell disease. Sickle hepatopathy, rather than hepatitis or biliary stones appeared to be primarily responsible for the extreme jaundice in at least four children and possibly in all six. Signs and symptoms were few, and laboratory abnormalities were not striking, other than marked hyperbilirubinemia (total serum bilirubin concentrations of 20.4-57.6 mg/dl with approximately one-half conjugated). The bilirubin level returned to normal in all patients in 4 days to 18 months, and all patients are currently well, without recurrence of hyperbilirubinemia or evidence of chronic liver disease. The cases described suggest that sickling within the liver, previously reported to be a serious and even fatal syndrome, usually is a benign and self-limited process.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7136 THE ROLE OF METABOLIC ACTIVATION FOR DRUG-INDUCED LIVER INJURIES. (Eng.) Dybing, E.; Mitchell, J. R. (Natl. Inst. Public Health, Oslo, Norway). *Acta Pharmacol. Toxicol. (Kbh.)* 41(Suppl. 2): 263-272; 1977.

The role of metabolic activation in drug-induced liver injury is discussed. Toxic reactive metabolites produced by microsomal cytochrome P-450 oxidation reactions have recently been implicated in the production of acute liver injury by paracetamol (a minor analgesic), furosemide (a diuretic), isoniazid (a tuberculostatic agent), and methyldopa (an antihypertensive agent. The identity of an arylating metabolite of paracetamol is uncertain, although an *N*-hydroxy derivative seems the most likely candidate. Presumably, the *N*-hydroxylated metabolite subsequently undergoes dehydration to a chemically reactive imidoquinone before arylating tissue macromolecules. Hepatic injury produced by furosemide apparently results from metabolic activation of the furan ring, possibly by an epoxidation similar to that proposed for the hepatocarcinogenic dihydrofuran aflatoxins. Increased risk of isoniazid-induced liver injury has been correlated with the rapid metabolism of this compound. In one study, 86% of 21 patients who recovered from isoniazid hepatitis displayed a rapid acetylator phenotype for isoniazid metabolism, whereas the expected distribution on a genetic basis was only 45%. In fast metabolizers, about 94% of the isoniazid is converted to acetylisoniazid, and it is hypothesized that acetylisoniazid is converted in the body to a chemically reactive form via activation of acetylhydrazine. Recently, liver microsomes from humans and laboratory animals have been shown to activate methyldopa to a potent arylating agent by a cytochrome P-450-generated superoxide anion.

7137 ACUTE STRUCTURAL HEPATIC ALTERATION DUE TO POISONS.

(Eng.) Thaler, H. (Wilhelminenspital, Vienna, Austria). *Acta Pharmacol. Toxicol. (Kbh.)* 41(Suppl. 2):253-261; 1977.

Hepatotoxins that cause acute hepatic alterations are reviewed. Five hours after carbon tetrachloride injury, liver cells show hydropic degeneration accompanied by a clear cytoplasm and pyknotic nuclei. The damage may progress to frank necrosis, with fatty change occurring in some surviving hepatocytes. Jaundice has been observed after the accidental ingestion of 4,4'-diaminodiphenylmethane, a hardener for epoxy resin. The overall appearance of liver biopsies was that of an inflammatory process, particularly in the portal areas, sometimes with cholangitis. After the ingestion of *Amanita* mushrooms, the liver shows centrilobular necrosis surrounded by nests of ceroid-containing phagocytes. In severe cases, the surviving liver cells show fatty change. The antibiotic tetracycline inhibits the synthesis of low-density lipoprotein-apoprotein, which removes triglycerides from the liver cell. After 2 weeks of treatment with tetracycline (275 mg 2 times/day, i.v.), hepatic triglycerides increased from 6.4 ± 1.8% to 11.2 ± 7.5%. Large tetracycline doses (3.5-6 g/day, i.v.) produce acute fatty liver and hepatorenal failure, resulting in death. Acetaminophen, the main constituent of many analgesic preparations, can cause fatal hepatic necrosis, but doses of at least 15 g are required. However, jaundice and hepatic necrosis have been observed after therapeutic doses (21 weeks of treatment, or 426.6 g). Halothane (an anesthetic agent), α-methyldopa (an antihypertensive agent), and oxyphenisatin (a constituent of many laxatives) cause liver changes that resemble viral hepatitis.

7138 NECROTIZING ANGIITIS AND HEPATITIS IN AN AMPHETAMINE ABUSER.

(Eng.) Richlin, D. M.; Saltzman, D. B.; Wills, J. (Presbyterian Hosp., New York, NY). *Delaware Med. J.* 49(8):469-477; 1977.

The case of a 23-yr-old amphetamine abuser with necrotizing angiitis and hepatitis is presented. The patient presented with recurrent abdominal pain, fever, and weight loss. He reported that he regularly used i.v. amphetamines. A liver-spleen scan revealed hepatomegaly, and selective celiac and right renal arteriograms revealed extensive, multiple aneurysms of the small and medium arteries. A hepatitis B antigen test was positive, but the serum complement levels were not depressed. The patient's serum alkaline phosphatase level was normal, and his bilirubin and SGOT levels were only marginally elevated. The patient recovered after antihypertensive therapy with methyldopa and furosemide. Although it has been previously suggested that those cases of necrotizing angiitis attributed to amphetamine abuse were really caused by hepatitis B virus, the hepatitis B virus infection in this patient is thought to be merely a coincidental finding; his extensive necrotizing angiitis is thought to have been amphetamine-induced.

7139 LIVER BIOPSIES FROM PSORIATICS RELATED TO METHOTREXATE THERAPY: 3. FINDINGS IN POST-METHOTREXATE LIVER BIOPSIES FROM 160 PSORIATICS.

(Eng.) Nyfors, A. (Dept. Dermatology, Finsen Inst., DK-2100, Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(4):511-518; 1977.

Liver biopsy findings for 160 psoriatics who had been treated with methotrexate (MTX) in single weekly p.o. doses of 25 mg maximum are reported. Among 92 patients who underwent a single biopsy and who had received a mean cumulative MTX dose of 2,287 mg (range, 50-5,075 mg), there were 6 cases of fibrosis and 1 case of cirrhosis. A comparison of these 7 patients with 13 patients with a normal liver histology revealed no statistically significant difference in cumulative MTX dose. However, the former were significantly older ($p<0.002$) and had a significantly higher admitted alcohol intake during MTX therapy ($p<0.016$). Among 68 patients who underwent serial biopsies and who had received a mean cumulative MTX dose of 3,940 mg (range, 325-8,355 mg) at the time of the latest liver biopsy, there were 14 cases of cirrhosis and 16 cases of fibrosis. When the 14 cirrhotics were compared with 9 patients with a normal liver histology, there was no statistically significant difference in the total MTX dose taken at the latest biopsy. However, the cirrhotics tended to be older ($p<0.058$), and they had consumed a significantly higher amount of alcohol during MTX therapy ($p<0.041$). Comparison of the single and serial-biopsy patients indicated that the prevalence of cirrhosis and fibrosis among MTX-treated psoriatics increases rapidly beyond a cumulative MTX dose of 2-4 g.

7140 HEPATIC DAMAGE ASSOCIATED WITH MINERAL OIL DEPOSITS. (Eng.) Blewitt, R. W.; Bradbury, K.; Greenall, M. J.; Burrow, H. (Dept. Pathology, Univ. Leeds, Leeds, England). *Gut* 18(6):476-479; 1977.

The case of a 33-yr-old man with hepatic inflammation and scarring associated with deposits of mineral oil in the portal triads is reported. During the course of an operation for a chronic duodenal ulcer, the liver was noted to be somewhat enlarged and irregular, and biopsies were taken from the porta hepatis and from an enlarged lymph node. The portal triads contained cystic spaces, some with a histiocytic lining, and vacuolated histiocytes; they were infiltrated by chronic inflammatory cells. The portal triads also showed increased fibrous tissue and some bile ductule proliferation. In the dilated medullary sinuses of the lymph node, plentiful histiocytes and scattered hemosiderin deposits were seen. Groups of cystic spaces, associated with many coarsely vacuolated histiocytes, were present in the cortex. Lipid analysis by thin layer chromatography showed spots with similar retardation factors to those of liquid paraffin, motor oil, and engineering oil. Cholesterol, tripalmitan, lecithin, palmitic acid, castor oil, and almond oil failed to migrate from the origin in several tests. The patient's only other recorded medical problem had been hemorrhoids, treated by sclerosant injections consisting of phenol in almond oil. He had taken 1 tablespoon of liquid paraffin as a laxative daily for about 2 months before his gastric operation. A further source of oil in this patient could have been respired oily aerosols.

7141 THERAPEUTIC ASPECTS OF PARACETAMOL OVERDOSE INCLUDING MANAGEMENT OF ACUTE LIVER FAILURE. (Eng.) Williams, R.; Davis, M. (King's Coll. Hosp. Medical Sch., London, England). *Acta Pharmacol. Toxicol. (Kbh.)* 41(Suppl. 2):300-310; 1977.

Methods for reducing the degree of liver damage after paracetamol overdose and for managing acute liver failure are reviewed. Patients should be hospitalized and observed for 48 hr, and serum aspartate aminotransferase, bilirubin, and prothrombin time should be estimated serially. All patients should be given i.v. infusions of 10% dextrose to avoid dehydration and calorie deprivation. The simplest ways of reducing the quantity of drug absorbed from the gastrointestinal tract and, thus, diminishing the degree of liver damage are by gastric lavage or by induced vomiting. Liver damage is preceded by depletion of hepatocellular reduced glutathione, allowing a hepatotoxic metabolite of paracetamol to bind to the cellular protein. Current treatment of patients after a paracetamol overdose is centered around the administration of compounds such as cysteamine or dimercaperol, which will substitute for the reduced glutathione. If hepatic failure intervenes, the patient should be treated by protein restriction, bowel sterilization, and replacement of clotting factors by infusions of fresh frozen plasma. Methods of temporary liver support are being developed based on charcoal hemoperfusion or hemodialysis.

7142 GRANULOMAS AND CHOLESTATIC-HEPATOCELLULAR INJURY ASSOCIATED WITH PHENYLBUTAZONE: REPORT OF TWO CASES. (Eng.) Ishak, K. G.; Kirchner, J. P.; Dhar, J. K. (Armed Forces Inst. Pathology, Washington, DC 20306). *Am. J. Dig. Dis.* 22(7):611-617; 1977.

The cases of two patients who developed combined cholestatic hepatocellular injury and noncaseating granulomas during phenylbutazone therapy are presented. The patients were men, aged 56 and 72 yr, who had received total doses of 3 and 14 g of phenylbutazone, resp. Both patients were also receiving tranquilizers (diazepam and chlordiazepoxide hydrochloride in each case, resp.). The drugs were discontinued when the patients developed nausea, pruritus, anorexia, and icterus. One patient had a macular rash, and both had peripheral blood eosinophilia. Liver biopsy specimens from both patients showed a combined hepatocellular and cholestatic injury, in addition to granulomas. Symptoms and signs subsided, and abnormal liver function tests returned to normal within 3 weeks after phenylbutazone was discontinued in both patients. Liver biopsy specimens 6 months later showed no granulomas or other pathologic changes. Cases of granulomatous hepatic reactions complicating phenylbutazone or oxyphenbutazone therapy are reviewed. Complete blood count and tests of hepatic function should be carried out before a patient is given either drug and at periodic intervals thereafter.

7143 HEPATITIS DUE TO MUSHROOM POISONING [Abstract]. (Eng.) Benhamou, J. P.; Ellinger, S. (Hopital Beaujon, Clichy, France). *Acta Pharmacol. Toxicol.* 41(Suppl. 2):299; 1977.

7144 QUANTITATIVE ASSESSMENT OF LIVER FUNCTION IMPAIRMENT IN HEPATOCELLULAR INJURY [Abstract]. (Eng.) Buch Andreasen, P. (Rigshospitalet, Copenhagen, Denmark). *Acta Pharmacol. Toxicol.* 41 (Suppl. 2):262; 1977.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

7145 FULMINANT HEPATITIS: A PRESENTATION OF WILSON'S DISEASE. (Eng.) Adler, R.; Mahnovski, V.; Heuser, E. T.; Presser, D. H.; Robinson, R. G. (Childrens Hosp. Los Angeles, 4650 Sunset Blvd., Los Angeles, CA 90027). *Am. J. Dis. Child.* 131(8):870-872; 1977.

The case of a 10-yr-old boy with fatal hepatic failure in whom Wilson's disease was confirmed at autopsy is presented. The patient presented with scleral icterus, right upper quadrant pain, recurrent epistaxis, and hepatosplenomegaly. His history included extensive exposure to animals and exposure to malathion 53 weeks prior to admission. Serum ceruloplasmin drawn on the second hospital day was reported at 11 mg/100 ml. The patient's condition was diagnosed as acute hepatic failure, and he was treated with ice-saline lavage, neomycin enemas, protein restriction, and i.v. fluids. On the third hospital day, ascites were detected, neurological deterioration progressed, and Babinski signs were present. The patient died in cardiopulmonary arrest within 3 weeks after the initial symptoms had developed. At autopsy, the pathological findings were typical of the intermediate or acute stage of the evolution of Wilson's disease; these included variably sized nodular liver, with collapse of the hepatocytes, fibrosis, inflammation, and bile duct proliferation. The liver copper level of 18.9 mg/100 g tissue wet weight, together with the ceruloplasmin level of 11 mg, were decisive in establishing the diagnosis of Wilson's disease. Wilson's disease must be included in the differential diagnosis of fulminating hepatic failure.

7146 PROTECTIVE EFFECT OF IMMUNE SERUM GLOBULIN (ISG) AGAINST HEPATITIS A INFECTION IN A NATURAL EPIDEMIC. (Eng.) Hall, W. T.; Madden, D. L.; Mundon, F. K.; Brandt, D. E. L.; Clarke, N. A. (Electro-Nucleonics Lab., Inc., Bethesda, MD 20014). *Am. J. Epidemiol.* 106(1):72-75; 1977.

In two wards of young patients housed at a hospital for the mentally retarded, 44 of 60 patients had no detectable antibody to hepatitis A prior to an epidemic that took place in 1970; 12 of 19 nonimmunized susceptible patients contracted the disease, while only 4 of 25 patients receiving human immune serum globulin (ISG) developed hepatitis. These four were probably infected with the virus prior to ISG administration. Of the 16 patients with pre-existing antibody, none showed any signs or symptoms of hepatitis.

7147 THE USE OF HEPATITIS B IMMUNE GLOBULIN (HBIG) IN THE PREVENTION OF HEPATITIS. (Eng.) Holland, P. V. (Blood Bank Dept., Clinical Center, NIH, Bethesda, MD 20014). *Acta Haematol. Pol.* 8(2):97-102; 1977.

Recommendations for the use of hepatitis B immune globulin (HBIG) in the prevention of hepatitis B are presented based on a literature review of clinical experiments with HBIG. HBIG should be given to the individual who had a small-dose, single-point exposure to the disease or intimate contact with an acutely ill hepatitis B surface antigen (HBsAg)-positive hepatitis patient. However, individuals who had anti-HBsAg at the time of exposure are immune to hepatitis B and need no immunoprophylaxis. HBIG also does not seem to be indicated for transfusion-associated hepatitis; this is largely a non-B problem, now that there is widespread HBsAg screening of blood donors. Since HBIG may suppress active immunity to hepatitis B, individuals who are going to be exposed to HBsAg-positive material on more than one occasion or who are in a chronically contaminated environment, such as a renal dialysis unit, may be better off receiving immune serum globulin (ISG) than HBIG. The significantly increased chance of obtaining residual immunity would counterbalance the slightly increased risk of overt hepatitis associated with ISG. The best and ultimate answer to the problem of hepatitis B prophylaxis is a safe and effective vaccine.

7148 CONTROLLED STUDIES WITH ACTH AND CORTICOSTEROIDS IN PATIENTS WITH CHOLESTATIC VIRAL HEPATITIS. (Ita.) Di Nola, F.; Bosio, G.; Marietti, G.; Veglio, V.; Baroni, L. (Ospedale per Infettivi Amedeo di Savoia, Torino, Italy). Italy). *Minerva Med.* 67(59):3903-3912; 1976.

Twenty-seven patients with cholestatic viral hepatitis were treated with ACTH, β-methasone, or a conventional dietary regimen supplemented with glucose, detoxifying agents, and vitamins. Treatment was continued for 21 days. Clinical and biochemical evaluations were made at the beginning and end of treatment, and they included parameters such as anorexia, icterus, nausea and vomiting, uremia, glycemia, total bilirubinemia, and levels of alkaline phosphatase, SGOT, and SGPT. Based on a statistical evaluation of the results by covariance and multivariance analyses, there was no advantage of hormone therapy over conventional dietary treatment of the disease.

7149 VERTICAL TRANSMISSION OF THE VIRUS OF HEPATITIS B AND NEONATAL HEPATIC CIRRHOSIS IN AN ARGENTINE FAMILY. (Eng.) Jorge, A.; Diaz, M.; Sanchez, D.; Filice, H.; Flores, A.; Perez-Elizalde, R. (Catedra de Clinica Medica III, Universidad Nacional de Cuye, Mendoza, Argentina). *Acta Hepatogastroenterol.* 24(3):162-166; 1977.

Vertical transmission of hepatitis B virus was observed in a family of six members. The mother was a healthy hepatitis B surface antigen (HBsAg) carrier, who also carried antibody to hepatitis B core antigen (anti-HBc). The father had chronic persistent hepatitis, was anti-HBc-positive, and carried antibody to hepatitis B surface antigen (anti-HBs). Two of the children developed neonatal cirrhosis. One child with cirrhosis was an anti-HBs carrier (anti-HBc was not determined), and the other was positive for anti-HBs and anti-HBc. Both died, and the diagnosis of cirrhosis was confirmed. The two other children were healthy anti-HBc carriers.

7150 HEPATITIS B: IMMUNOPATHOLOGY IN DIFFERENT CLINICAL COURSES OF THE DISEASE. (Ger.)

Bianchi, L.; Gudat, F. (Institut fur Pathologie, Schonbeinstrasse 40, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107(27):929-935; 1977.

The presence of nuclear hepatitis B core antigen (HBcAg) and cytoplasmic hepatitis B surface antigen (HBsAg) in the liver tissue and of Dane particles and anti-HBc titers in the blood of 62 patients with acute and chronic HB was determined. Four reaction patterns of diagnostic and prognostic significance were found. (1) The elimination-type pattern is found in acute, self-limiting viral hepatitis. There are no viral components in the liver tissue at the height of the disease, despite seropositivity. (2) The HBc-predominance type, as seen in immunosuppressed kidney transplant patients and silent chronic, nonaggressive hepatitis (unspecific reactive or chronic persisting hepatitis patients), is associated with marked expression of HBcAg (60-100% of hepatocyte nuclei) and cytoplasmic HBsAg in 0-20% of cells. This type may also occur without exogenous immunosuppression or without a detectable endogenous immune defect. (3) The HBs-predominance type, with HBsAg occurring in up to 80% of the hepatocytes, is associated with a second type of silent chronic nonaggressive hepatitis. (4) The HBc+s type is found in aggressive types of hepatitis, and up to 70% HBcAg and 30% cytoplasmic HBsAg can be expressed. Nonaggressive chronic hepatitis can be linked to types 2, 3, and 4. Anti-HBc titers were elevated in both aggressive and nonaggressive hepatitis, but they were usually negative in immunosuppressed patients and highest in those with chronic aggressive hepatitis. HBcAg in liver tissue was constantly associated with Dane particles in the blood. In view of this association, two forms of chronic HB virus infection can be distinguished: (1) chronic infective forms, including HBc+s-type aggressive hepatitis, and HBc-predominance-type nonaggressive hepatitis and (2) variants with no or low infectivity (HBs-predominance-type chronic nonaggressive hepatitis). The reaction pattern is probably determined by the immune response, the key mechanism being the elimination of affected cells. Between efficient elimination (elimination type) and effective immunosuppression (HBc-predominance type), a graded elimination is found in chronic forms (HBs-predominance and HBc+s types), which explains the persistence and, possibly, aggressiveness of HB virus infection.

7151 LEUKOCYTE MIGRATION INHIBITION TEST IN HBs-POSITIVE AND HBs-NEGATIVE CHRONIC LIVER DISEASE USING AN HBsAg PREPARATION. (Ita.)

Craxi, A.; Genova, G.; Spano, C.; Chiarini, A.; Pagliaro, L. (Ospedale V. Cervello, Palermo, Italy). *Minerva Gastroenterol.* 22(3):253-256; 1976.

The leukocyte migration inhibition (LMI) test in agarose was applied to 81 patients with chronic liver disease. Four patients had cholestasis, and all were sero negative for hepatitis B surface antigen (HBsAg); 7 had chronic persisting hepatitis, 5 were HBsAg-negative and 2 HBsAg-positive; 44 had active or inactive cirrhosis, 33 HBsAg-negative and 11 HBsAg-positive; 16 had chronic active hepatitis (CAH), 10 HBsAg-negative and 6 HBsAg-positive; and 16 had hepatoma, 9 HBsAg-negative and 1 HBsAg-positive. Fifty percent of the HBsAg-positive CAH patients and 63% of the HBsAg-positive cirrhosis patients had positive LMI test results. In these patients, therefore, it is not possible to demonstrate a depression of cellular immunity as a hypothetical basis for the persistence of infection. Fifty percent of the HBsAg-negative CAH patients and 18% of the HBsAg-negative cirrhosis patients also had positive LMI test results. These patients, although antigenically negative, may have been infected with hepatitis B virus. There was an inverse relationship between a positive LMI test result and anti-hepatitis B core antigen (HBcAg) levels in all HBsAg-positive patients. This relationship could not be verified in HBsAg-negative patients because only a small number had anti-HBcAg in their serum.

7152 HEPATITIS-B ANTIGEN IN THE LIVER: IMMUNOFLUORESCENCE STUDIES. (Ger.)

Storch, W. (Neurologische Klinik, Karl-Marx-Universitat, Karl-Marx-Stadter-Strasse 50, A 2, DDR-7039 Leipzig, E. Germany). *Dtsch. Gesundheitsw.* 32(28):1304-1310; 1977.

Liver biopsy specimens from 71 patients with and without liver diseases were investigated for hepatitis B antigen (HBAg) by an immunofluorescence method. Fifteen patients had acute viral hepatitis (AVH), 2 chronic persisting hepatitis (CPH), 10 chronic aggressive hepatitis (CAH), 9 liver cirrhosis (LC), 8 unspecific reactive hepatitis (URH), 20 other or no liver diseases, and 7 were clinically healthy HBAg carriers. Twenty-one patients were positive for liver HBAg, 33 for serum HBAg. There was no marked correlation between serum and liver HBAg; both tests were positive in 15 patients and negative in 32; 6 serum-negative patients had HBAg in their livers, and 18 serum-positive patients had none. HBAg was found in the hepatocyte nuclei in one patient (in <20% of the hepatocytes), in the cytoplasm in 13 (in <20% of the hepatocytes in 2, >20% in 11), in the nucleus and cytoplasm in three, in the hepatocyte membrane and/or sinusoids in two, and simultaneously in the cytoplasm of hepatocytes, sinusoids, and necroses in two. Differences in localization may be due primarily to the specificity of the anti-HBAg sera used (human and rabbit anti-HBAg of different origin). There was no clearcut correlation between clinical and histological diagnosis and the number of positive cells, even though the latter was substantially higher in "healthy" carriers than in patients with liver diseases. Core antigen (HBcAg) was found mainly in AVH and CAH. HBcAg correlated with nude intranuclear bodies measuring 20-25 nm, but surface HBAg correlated with amorphous and filamentous material in the increased smooth endoplasmic reticulum of "ground glass" hepatocytes. The presence of HBAg in the hepatocytes of serum-positive patients may indicate a persisting HB virus infection and/or a disturbance of the immunological elimination of infected cells.

7153 HEPATITIS Bs ANTIGEN (HBsAg) DURING PREGNANCY.

(Eng.) Hill, L. M.; Marcus, W. M.; Kempers, R. D.; Taswell, H. F. (Mayo Clinic, 200 First St. S.W., Rochester, MN 55901). *Obstet. Gynecol.* 50(1):78-81; 1977.

Three patients with serum hepatitis during pregnancy are described. The first patient first became pregnant 1 yr after an episode of anicteric viral hepatitis; this pregnancy ended in a spontaneous abortion. The patient's serial transaminase values remained stable during her second pregnancy, although she was hepatitis B surface antigen (HBsAg)-positive. She was clinically well, and her liver disease was classified as consistent with chronic persistent hepatitis. Her child was found to have HBsAG at the age of 3 months. He is developing normally at age 4 yr. The patient's third child was HBsAg-negative at birth and was treated with hepatitis B immune globulin; he remains HBsAg-negative at age 14 months. The second patient had acute hepatitis during the eighth month of pregnancy, and was HBsAg-positive at delivery. Her child became HBsAG-positive at 6 weeks of age. He has been clinically well, although mild liver function abnormalities persist at 3 yr of age. The third patient was HBsAg-positive during her pregnancy, but antigen-negative at delivery. The amniotic fluid 3 weeks before delivery was HBsAg-positive, but the child was HBsAg-negative at birth. She received hepatitis B immune globulin at 1 day of age. All patients had a normal spontaneous vaginal delivery. None of the infants was breast fed. Abortion is not indicated for either the patient with acute hepatitis B or the chronic HBsAg carrier. Cesarean section should not be performed in the hope of preventing the fetal infection that frequently occurs, but should be performed only for standard fetal and maternal indications. Routine precautions for hepatitis should be rigidly enforced during the labor, delivery, and postpartum care of the HBsAg-positive patient. Treatment with hepatitis B immune globulin may be effective in preventing neonatal hepatitis type B.

7154 METHODS FOR DETECTION OF HEPATITIS B SURFACE ANTIGEN IN PARAFFIN SECTIONS OF LIVER: A GUIDELINE FOR THEIR USE.

(Eng.) Sumithran, E. (Dept. Pathology, Univ. Malaya, Kuala Lumpur, Malaysia). *J. Clin. Pathol.* 30(5):460-463; 1977.

Methods for the localization of hepatitis B surface antigen (HBsAg) in paraffin sections of the liver were compared, and suggestions for their use are outlined. The methods include the detection of ground glass-positive hepatocytes, the use of Shikata orcein stain, and immunoperoxidase and immunofluorescent techniques. A comparative study of the different methods on 20 livers showed the orcein stain to be the method of choice for routine use. The Shikata stain is not only specific but is relatively inexpensive, easily performed, and stains out distinct cytoplasmic inclusions even in stored formalin-fixed livers, old paraffin blocks, and autolysed livers. Since HBsAg is irregularly distributed in the liver, adequate sampling is necessary to prevent false negatives; when sufficient tissue is available at least five blocks should be examined before a case is labeled as HBsAg-negative.

7155 INCIDENCE OF HBsAG, ANTI-HBs AND SUBTYPES ad AND ay IN A GENERAL HOSPITAL: CORRELATION WITH CLINICAL DATA AND ITS SIGNIFICANCE AS A PUBLIC HEALTH PROBLEM.

(Eng.) Telischi, M.; Steigmann, F.; Canlas, N.; Foemmel, R.; Decker, R.; Ling, C. (Cook County Hosp., 1825 W. Harrison St., Chicago, IL 60612). *Am. J. Gastroenterol.* 67(5):449-455; 1977.

The incidence of hepatitis B surface antigen (HBsAg) and anti-HBsAg among 9,418 individuals comprising new hospital admissions, new employees, and blood donors in a general hospital was investigated. The incidence of HBsAg among 101 patients with acute hepatitis, 363 patients with liver disease (other than hepatitis) and gastrointestinal problems, 6,731 newly admitted patients with all types of medical and surgical entities, 1,824 volunteer blood donors, and 399 newly employed persons were 69.3%, 5.2%, 2.2%, 1%, and 4.0%, resp. The incidence of anti-HBsAg in the acute hepatitis patients was 17.8% compared with 12.7% for the liver-gastrointestinal patients and 30.3% for the newly admitted patients. No anti-HBsAg tests were done on employees or donors. Subtyping was performed on acutely ill patients and carriers. Of 46 patients with HBsAg-positive acute hepatitis, 31 had subtype *ay*, 15 subtype *ad*. Of 30 nonhepatitis patients positive for HBsAg, 5 had subtype *ay*, 25 subtype *ad*. Of 17 acute hepatitis patients with anti-HBsAg, 5 had *ay*, 12 *ad*, and among 92 nonhepatitis patients with anti-HBsAg, 18 had *ay*, 74 *ad*. Subtype *ay* predominated in the acute hepatitis cases, but subtype *ad*, was found in approximately 70% of the other cases. No significant correlation was noted between subtypes and duration of symptoms, duration of HBsAg antigenemia, length of hospital stay, or severity of clinical disease. The incidence of

HBsAg-positive persons detected at this hospital is concluded to be high. Despite this, no significant epidemics of hepatitis have occurred. This appears to be partly due to the fact that a comparatively high number of individuals coming to this hospital have an immunity to this infection and partly due to the institution of preventive measures.

7156 HBsAg AND HBcAg IN VIRUS-LIKE PARTICLES DISCOVERED BY IMMUNOFLUORESCENCE IN LIVER BIOPSY SPECIMENS FROM ACUTE AND CHRONIC HEPATITIS PATIENTS. (Ita.) Rizzetto, M.; Bonino, F.; Toselli, M.; Verme, G. (Ospedale Mauriziano, Turin, Italy). *Minerva Gastroenterol.* 22(3):241-244; 1976.

Liver biopsy specimens from patients with acute and chronic hepatitis were examined by immunofluorescence to determine the presence of surface and core antigen to hepatitis B virus (HBsAg or HBcAg). Of the 109 specimens, 74 were from patients seronegative for HBAg and 35 were from patients seropositive for the antigen. None of the 74 negative patients were positive for HBsAg or HBcAg by immunofluorescence. Biopsy specimens from 14/35 positive patients were also negative for HBsAg and HBcAg. In one group of positive patients, HBsAg was diffused throughout the cytoplasm, but it was not present in the border cells. In six patients, HBsAg was in discrete locations in the cytoplasm, in small groups or in single cells, and in the border cells. These patients were HBcAg-negative. In another group of 10 positive patients, HBcAg was found in the nucleus. Seven of these patients were also capable of fixing complement *in vitro*. The localization of HBsAg exclusively in the cytoplasm indicates an undamaged or mildly inflamed liver. The presence of HBsAg in the cytoplasm and the border cells is associated with chronic hepatitis, either active or persisting. The presence of HBcAg in the nucleus is associated with active hepatitis, with or without cirrhosis, and it is correlated with degree of aggressiveness of the disease. The significance of the ability of HBcAg-positive cells to fix complement *in vitro* has not been determined.

7157 DIFFERENCE IN THE DISTRIBUTION OF e ANTIGEN AMONG DIFFERENT ETHNIC GROUPS IN A POPULATION OF BLOOD DONORS. (Eng.) Richer, G.; Phaneuf, D.; Boisvert, F.; Guevin, R.; Viallet, A. (Hopital Saint-Luc, 1058 St. Denis St., Montreal, Quebec H2X 3J4, Canada). *Can. Med. Assoc. J.* 116(7): 757-759; 1977.

The sera of 368 blood donors positive for hepatitis B surface antigen in the Montreal area and 310 people living in close contact with them were screened for the presence of e antigen and antibody (anti-e), using Ouchterlony wells and counterimmunoelectrophoresis. Neither e nor anti-e was found in the absence of markers of hepatitis B virus (HBV). The e antigen was detected in 23 blood donors and anti-e in 313; 32 were negative for both markers. Of the 368 blood donors, 330 were of French origin and 38 from other ethnic groups. The 23 e-positive subjects were unequally distributed among the ethnic groups; only 4.2% were recruited among the French group, while 23.7% were recruited among other ethnic groups ($p < 0.001$). This difference among ethnic groups might be related to the vertical or horizontal mode of dissemination of HBV infection.

7158 PERIPHERAL T AND B LYMPHOCYTE ROSETTING IN ACUTE INFECTIVE HEPATITIS AND EVALUATION OF A PLASMA INHIBITORY FACTOR. (Eng.) Mahalanabis, D.; Jalan, K. N.; Maitra, T. K.; Agarwal, S. K.; Bhattacharyya, S. (Calcutta Medical Res. Inst., Diamond Harbour Rd., Calcutta, India). *Indian J. Med. Res.* 64(12):1723-1727; 1976.

Chronic Hepatitis

7165 AUTOANTIBODIES IN THE DIAGNOSIS OF LIVER DISEASES. (Ger.) Lehmann, H. U.; Renger, F.; Morenz, J.; Zugehor, M. (Medizinische Klinik, Medizinische Akademie "Carl Gustav Carus," Fetscherstrasse 74, DDR-8019 Dresden, E. Germany). *Dtsch. Gesundheitsw.* 32(30):1415-1419; 1977.

Sera from 397 patients with liver diseases and 303 patients with other, nonspecified diseases (control group) were investigated for autoantibodies to smooth muscle (SM-AAB), mitochondria (M-AAB), and cell nuclei (N-AAB) and for hepatitis B antigen (HBAg). The positive test rates were 57/97 for M-AAB, 8/97 for SM-AAB, 2/97 for N-AAB, and 38/97 for HBAg in patients with infectious hepatitis. The corresponding rates were 16/30, 3/30, 0/30, and 15/30 among patients with chronic persisting hepatitis; 48/63, 19/63, 8/63, and 22/63 in chronic active hepatitis; 71/112, 15/112, 3/112, and 12/112 in liver cirrhosis; 19/19, 4/19, 3/19, and 0/19 in primary biliary cirrhosis; 11/21, 1/21, 0/21, and 0/21 in secondary biliary cirrhosis; and 25/44, 5/44, 1/44, and 0/44 in fatty degeneration of the liver. All tests were negative in the 11 patients with alcoholic liver cirrhosis. The incidences of positive tests were 119/303 for M-AAB, 11/303 for SM-AAB, 6/303 for N-AAB, and 0/303 for HBAg in the control group. Autoantibody titers were low in all HBAg-positive cases. The total serum titer (TST) of the autoantibodies (sum of the ranges for each individual titer) was found to be of diagnostic value. Primary biliary cirrhosis and autoimmune chronic active hepatitis can be ruled out if the TST=0. In patients suspected of having either chronic persisting or chronic active hepatitis, a TST$\geq$640 probably indicates chronic active hepatitis.

7166 SIGNIFICANCE OF "GROUND GLASS" HEPATOCYTES IN LIVER BIOPSY SPECIMENS FROM CHILDREN WITH CHRONIC HEPATITIS. (Ger.) Hinkel, G. K.; Probsthain, A. R.; Roschlau, G.; Stotzner, H.; Kemmer, Chr. (Medizinische Akademie "Carl Gustav Carus," Fetscherstrasse 74, DDR-8019 Dresden, E. Germany). *Dtsch. Gesundheitsw.* 32 (29):1365-1370; 1977.

One hundred fifty-eight liver biopsy specimens from 34 children with chronic persisting hepatitis (CPH) and 11 children with chronic aggressive hepatitis (CAH) were investigated for "ground glass" hepatocytes (GGH). The sections were stained with hematoxylin-eosin. Nine patients with CPH and eight with CAH were positive for hepatitis B surface antigen (HBsAg), and of these patients, four with CPH and three with CAH had GGH. Although all seven patients with GGH were HBsAg-positive, none had anti-HBs antibodies. When the GGH were detected, most of the seven patients had GOT and GPT levels of <50 IU and 50-150 IU, resp.; only two had GOT levels and one a GPT level of >150 IU. No definite correlation was found between the occurrence of GGH and the age of the patients, therapy, γ-globulin levels, and humoral immunological parameters. In all patients with GGH, IgG levels were around 2S and IgM and IgA levels were above 3S. Typical GGH with a diffuse distribution pattern were found mainly in CPH of 1-2 yr duration. Electron microscopy of biopsy specimens from four children with GGH revealed proliferation of the smooth endoplasmic reticulum, and an accumulation of perigranular, filamentous and partially ring-shaped material and individual, dense, intracisternal particles. Investigations of GGH in larger series of patients will be necessary to determine its significance.

7167 CHRONIC HEPATITIS IN HEMOPHILIA. (Eng.) Seeff, L. B.; Hoofnagle, J. (Veterans Admin. Hosp., Washington, DC). *Ann. Intern. Med.* 86(6):818-819; 1977.

The occurrence of chronic hepatitis in patients with hemophilia is discussed and reviewed. The first report to suggest that chronic hepatitis might be common in patients with hemophilia showed that 45% of 91 hemophiliacs had moderate elevations of serum transaminases, 41% had abnormal BSP retention, 8% were hepatitis B surface antigen (HBsAg)-positive, and 66% were anti-HBs-positive. None had symptoms of liver disease. The existence of chronic liver disease was not confirmed by liver biopsy. In a recent study, however, liver biopsies in three of six hemophiliacs with prolonged abnormal liver function tests showed the features of chronic active hepatitis; in the remaining three, the liver biopsy showed features of chronic persistent hepatitis. Chronic infection with hepatitis B virus is clearly one cause for the disease in these patients, but appears to account for less than one-fourth of the cases. Many of the remaining cases may result from chronic infection with the virus(es) of type non-A, non-B hepatitis. In addition, the stabilizing chemicals (phthalates, polyethylene glycol), used in the various stages of clotting factor concentrate preparation, deserve investigation.

7168 CHRONIC ACTIVE LIVER DISEASE: DEFINITION, DIAGNOSIS, AND MANAGEMENT. (Eng.) Whitcomb, F. F. (Lahey Clinic Foundation, Boston, MA). *Lahey Clin. Found. Bull.* 26(2):69-77; 1977.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7171 RATIO OF PLASMA ALPHA AMINO-n-BUTYRIC ACID TO LEUCINE AS AN EMPIRICAL MARKER OF ALCOHOLISM: DIAGNOSTIC VALUE. (Eng.) Morgan, M. Y.; Milsom, J. P.; Sherlock, S. (Royal Free Hosp. Sch. Medicine, Univ. London, Hampstead, London NW3 2QG, England). *Science* 197(4309):1183-1185; 1977.

The value of determining the ratio of plasma alpha amino-*n*-butyric acid to leucine (A/L ratio) in the diagnosis of alcoholism was studied in 50 controls, 43 alcoholics with various degrees of liver damage, and 77 patients with nonalcoholic liver and biliary tract disease. The relation between the A/L ratio and several parameters of liver cell damage were also studied, and the changes that occur in the ratio postprandially and diurnally were observed. The A/L ratio in the alcoholic patients (0.225 ± 0.110) was significantly increased in comparison with that of the controls (0.181 ± 0.058, $p<0.025$). The A/L ratio was raised in the alcoholic patients, regardless of whether or not they had been recently drinking. In the 22 alcoholics with fatty change only, the A/L ratio was not significantly different from that of controls, regardless of recent alcohol abuse. In the alcoholics with more advanced liver damage, the ratio was raised both in patients who had been drinking recently and in those who had not. Among the 77 patients with nonalcoholic liver and biliary tract disease, the mean A/L ratio was raised in those with active chronic hepatitis, primary biliary cirrhosis, cryptogenic cirrhosis, and acute type A hepatitis, but not in the group with primarily biliary tract disease. In the alcoholic patients there was no significant correlation between the plasma A/L ratio and the standard liver function tests or the degree of histological hepatocellular damage. Thus, the A/L ratio is not a sensitive index of hepatocellular dysfunction. The results indicate that the A/L ratio cannot be used as an index of alcoholism.

7172 ENZYME TESTS FOR ALCOHOLISM. (Eng.) Rosalki, S. B. (St. Mary's Hosp., London W2, England). *Rev. Epidemiol. Sante Publique* 25(2):147-158; 1977.

Enzyme tests for detecting alcoholism are reviewed. Elevated serum γ-glutamyltransferase (GGTP) levels can be used to detect early alcoholism, before the onset of abnormal liver function. With continued drinking, hepatocellular injury and biliary stasis contribute to serum GGTP elevation, which may then be accompanied by increased levels of serum aspartate and alanine transaminase from hepatocellular injury and of alkaline phosphatase from biliary stasis. Serum GGTP levels were analyzed in four patient groups with increasing levels of alcohol consumption and clinical severity: outpatient heavy drinkers, outpatient alcoholics, alcoholics admitted for drying-out, and alcoholics admitted for complications, including cirrhosis. The results showed elevated serum GGTP levels in 85%, 89%, 85%, and 81% of the respective groups for an overall incidence of 85%. The fact that the incidence of increased GGTP levels remains nearly constant in each patient group underlines the fact that GGTP is a test for excess alcohol consumption, independent of the liver damage or behavioral changes that separate the alcoholic from the heavy drinker. The sensitivity of elevated GGTP is evidenced by the fact that consumption of 1 g of alcohol/kg body weight over an evening by normal subjects is sufficient to produce a transient elevation in GGTP (not >3 U/l at 37 C) that reverts to normal within 19 hr after the cessation of drinking. About 3 weeks of daily alcohol consumption at this dose is required before pathological levels are seen. When an alcoholic stops drinking, the GGTP level generally shows a 50% reduction within 2 weeks and is near normal within 5 weeks. However, a more persistent elevation is observed in the presence of underlying cirrhosis. Enzymes useful for detecting vitamin B deficiency in alcoholics are transketolase, glutathione reductase, and aspartate transaminase.

7173 HEPATIC TRIGLYCERIDE LIPASE DEFICIENCY IN LIVER DISEASE. (Eng.) Freeman, M.; Kuiken, L.; Ragland, J. B.; Sabesin, S. M. (Univ. Tennessee Center for the Health Sciences, Memphis, TN 38163). *Lipids* 12(5):443-445; 1977.

The activity of postheparin lipases was evaluated in 10 patients with alcoholic hepatitis or viral hepatitis and in 9 controls. Lipoprotein lipase and hepatic triglyceride lipase were differentiated by assay under high and low salt conditions and also by separation on heparin-agarose affinity chromatography columns. The mean activity of hepatic triglyceride lipase in the sera of liver disease patients was only 21-24% of the mean of controls, but lipoprotein lipase in the patients' sera was similar to that in controls. Hepatic triglyceride lipase deficiency may partially account for the accumulation of a triglyceride-rich low-density lipoprotein in liver disease.

7174 EFFECTS OF ACUTE ETHANOL INTAKE ON LIVER MORPHOLOGY AND METABOLISM. (Eng.) Morland, J. (Inst. Medical Biology, Univ. Tromso, Tromso, Norway). *Acta Pharmacol. Toxicol. (Kbh.)* 41(Suppl. 2):273-281; 1977.

The effects of acute ethanol intake on liver morphology and metabolism are discussed. The metabolism of ethanol, which occurs mainly in the liver, occurs via alcohol dehydrogenase and acetaldehyde dehydrogenase, leading to the production of acetaldehyde, acetate, and acetyl-coenzyme A. An important reaction accompanying ethanol oxidation is the reduction of NAD to NADH, which increases the ratio of reduced:oxidized coenzyme ratio. A single dose of ethanol can produce changes in triglyceride metabolism, the citric acid cycle, glucose production, amino acid transport, urea synthesis, protein synthesis, enzyme leakage, and drug metabolism. Morphologically, these biochemical changes may be accompanied by fatty liver and mitochondrial and lysosomal alterations. The effect of ethanol on blood glucose depends on the nutritional status of the individual, producing hypoglycemia in fasting subjects but not in well-nourished subjects. In chronic drinkers, acute ethanol intake can lead to an increased enzyme leakage, an increased net production of acetaldehyde, and acute massive liver necrosis.

7175 PLATYPNEA AND HYPOXEMIA IN LAENNEC'S CIRRHOSIS OF THE LIVER. (Eng.) Santiago, S. M., Jr.; Dlaton, J. W., Jr. (Wadsworth Veterans Admin. Hosp., Wilshire and Sawtelle Blvd., Los Angeles, CA 90073). *South Med. J.* 70(4):510-512; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

7177 DETECTION OF MICROSOMAL ANTIBODIES IN CHRONIC LIVER DISEASES BY OPTICAL IMMUNOFLUORESCENCE. (Ger.) Storch, W.; Petzold, H. (Neurologische Klinik, Karl-Marx-Universitat, Emilienstrasse 30, DDR-701 Leipzig, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 36(3/4):137-139; 1976.

Over 1,000 serum samples from patients with chronic liver diseases were tested for autoantibodies by optical immunofluorescence. Composite blocks of rat kidneys, liver, and stomach and mouse kidneys were used as the antigenic substrate, and labeled anti-human IgG from rabbits was used as the conjugate. Reproducible, simultaneous, specific diffuse cytoplasmic fluorescence of the proximal renal tubule cells (mainly of the P_3 segment) and hepatocytes was found in 18 patients (10 with liver cirrhosis, 7 with chronic acitve hepatitis, 1 with chronic persisting hepatitis). Microsomal antibodies do not appear to form a homogeneous group.

7178 CHRONOBIOLOGICAL STUDY ON SERUM IMMUNOREACTIVE GASTRIN RIA LEVELS IN PATIENTS WITH LIVER CIRRHOSIS. (Eng.) Tarquini, B.; Anichini, P.; Brocchi, A.; Falchi, S.; Tommasi, S. (Istituto di Semeiotica Medica, Villa Monna Tessa, Viale Pieraccini, 18, I-50139 Firenze, Italy). *Digestion* 15(5):447-451; 1977.

To study possible circadian rhythms in gastrin release, serum gastrin levels were measured in six patients with liver cirrhosis on 3 consecutive days and in 14 normal controls on 1 day. The study was carried out after the subjects had been kept on a standardized diet for at least 7 days. Blood samples were drawn every 4 hr. In patients as well as in controls, a significant serum gastrin circadian rhythm was noted. The daily mean serum gastrin levels of patients were not significantly different from those of controls. These results suggest a secondary role of the liver in gastrin metabolism.

7179 REINFUSION OF ASCITIC FLUID IN THE TREATMENT OF CIRRHOTIC ASCITES. (Ger.) Standaert, L. O. (Abteilung fur Interne Krankheiten, St. Elisabeth-Hospitals, Lange Lozanastraat 222, B-2000 Antwerp 1, Belgium). *Dtsch. Z. Verdau Stoffwechselkr.* 36(3/4):153-155; 1976.

Eleven patients with ascites caused by liver cirrhosis were treated by a reinfusion of concentrated cirrhotic liquid. The ascitic liquid was aspirated by a peritoneal catheter at a rate of 20 ml/min, and water and electrolytes were separated in a closed-cycle multimembrane ultrafilter. The resulting liquid, concentrated by a factor of 2.15, was reinfused into the subclavian artery at a rate of 250-300 ml/min. The reinfusion lasted an average of 8 hr, and during this time the patients also received furosemide (40 mg) and cardiac stimulants. The treatment was well-tolerated, even though nearly all the patients developed slight hypertension. A small drop in hemoglobin concentration and hematocrit was seen in all patients immediately after reinfusion and five developed thrombocytopenia. Liver function showed no change. Hepatitis B antigen was found in the ascitic fluid, but not in the ultrafiltrate of three patients. Some patients responded to conventional treatment (drainage of ascitic liquid) or remained "dry" after reinfusion, but others required repeated reinfusions of longer durations. The results with a larger series indicate increased 1- and 2-yr survival rates after reinfusion. This new therapeutic method is indicated for patients with decompensated cirrhosis, hypovolemia, hypoproteinemia, hyponatremia, and functional renal insufficiency. Severe oliguria, uremia, hyperammonemia, and jaundice are not counterindications, but severe cardiac insufficiency, peritoneal infection, and sepsis are.

7180 PERITONEOVENOUS SHUNTING FOR ASCITES. (Eng.) Reinhardt, G. F.; Stanley, M. M. (Veterans Admin. Hosp., Hines, IL). *Surg. Gynecol. Obstet.* 145(3):419-424; 1977.

The use of a peritoneovenous shunt for relieving dietary, diuretic-resistant ascites in 25 adult men with alcoholic cirrhosis is reported. A pressure-sensitive valve, which is incorporated in the shunt, permits flow in one direction only, and its characteristics are such that an i.p. pressure that exceeds central venous pressure by 3-5 cm of water will allow flow of ascitic fluid into the central venous system. The shunt can be performed safely under local anesthesia. All of the patients tolerated the procedure well. Three patients in hepatic coma survived the procedure, although all eventually died of progressive hepatic failure during the same hospitalization period. Since the course of patients with such severe hepatic failure does not appear to be favorably influenced by the shunt, its use in patients with severe encephalopathy is not recommended. A good response to the shunt procedure was observed in 19/22 patients discharged with shunts in place. These 19 patients showed a sustained normal pattern of diuresis and relief of disabling ascites. Two patients had a fair but incomplete response to the shunt procedure. One additional patient with a fair response returned to alcoholism and died 4 months after the surgical procedure. The average length of follow-up time in the 18 surviving outpatients was 10 months (range 3-21 months).

7181 ULTRASTRUCTURE OF HEPATOCELLULAR CARCINOMA IN A CIRRHOTIC LIVER. (Eng.) Livni, N.; Behar, A.; Brautbar, N. (Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel). *Isr. J. Med. Sci.* 13(6):590-599; 1977.

Light and electron microscopic observations of biopsy material from a 23-yr-old woman with hepatocellular carcinoma in a cirrhotic liver are reported. Although the hepatoma cells shared many similarities with nonneoplastic hepatocytes, they showed conspicuous alterations, such as intranuclear pseudoinclusions and lipoid material, abundant small fat droplets and glycogen in the cytoplasm, high mitotic activity, and an increased nuclear/cytoplasmic ratio. The rough endoplasmic reticulum and Golgi apparatus were prominent in the hepatoma cells, and the sinusoids showed capillarization. The latter was observed in cirrhotic as well as in neoplastic areas; however, in neoplastic liver tissue, this transformation consisted not only of the deposition of basement membrane-like material, but also of the appearance of junctions between endothelial cells. Annulate lamellae were occasionally seen in the hepatoma cells. Microtubules, which were present in small amounts in normal hepatocytes, were abundant in the hepatoma cells, and they appeared as long filamentous structures of 15-20 nm diameter with a center of low electron density.

7182 HEPATIC ENCEPHALOPATHY: HEMODYNAMIC AND METABOLIC STUDY OF THE INFLUENCES OF AMMONIA AND L-DOPA. (Fre.) Baldy-Moulinier, M.; Bories, Ph.; Michel, H.; Passouant, P. (Institut de biologie, boulevard Henri IV, F 34000 Montpellier, France). *Rev. Neurol. (Paris)* 133(3):175-189; 1977.

Cerebral blood flow (CBF) and cerebral energy metabolism (CEM) were studied in 15 patients with cirrhosis (12 of whom had hepatic encephalopathy), 3 chronic alcoholism patients without cirrhosis, and 1 normal subject. Measurements were made before and after i.v. administration of ammonium chloride and/or L-dopa. Although all subjects had a normal or near normal CBF, cerebral O_2 consumption was significantly decreased in the cirrhotic patients, even after correcting for their lower hemoglobin values. These lower O_2 values were not directly related to the hypocapnia, hyperlactacidemia, and elevation of phenylalanine and tyrosine levels also found in cirrhotic patients. Ammonium chloride reduced the CBF in all patients, but its effect on CEM was slight. L-dopa had no effect, but it was able to correct the effects of ammonium chloride on CBF and CEM. These results indicate that symptoms of hepatic encephalopathy are not directly related to a reduced CEM and they are not dependent on a blockage of dopaminergic synapses, but that the formation of cerebral arteriovenous shunts may be implicated.

7183 STUDY OF PULMONARY ANOMALIES DURING LIVER CIRRHOSIS.

(Fre.) Seigneuric, Ch. (Faculte de medecine de Dijon, Dijon, France). *Rev. Fr. Gastroenterol.* 126(2):53-54; 1977.

Pulmonary function was studied in 71 patients with liver cirrhosis. Clinical abnormalities were rare (cyanosis in 4, digital hippocratism in 6), but respiratory function was impaired in 65 of the patients. Circulatory abnormalities consisted of arteriovenous, bronchopulmonary, and portopulmonary shunts; alveolar and pleural vasodilation; and pleural angiomas. Restrictive and/or obstructive ventilatory syndromes, diffusion problems, and ventilation-perfusion disequilibria were frequent. Gaseous alkalosis was found in 55 patients. These pulmonary abnormalities may lead to potassium depletion, hemodynamic perturbations, cardiac failure, and digestive hemorrhages, and they must be carefully monitored in cirrhotic patients.

7184 A STUDY OF THE INTRAHEPATIC VASCULATURE IN THE HUMAN FETUS, IN THE NORMAL ADULT AND IN ADULTS WITH PORTAL CIRRHOSIS.

(Eng.) Hidayet, M. A.; Wahid, H. A.; Hidayet, A. M.; Hidayet, N. M. (Faculties Medicine, Univ. Western Ontario, London, Ontario, Canada). *Surg. Gynecol. Obstet.* 145(3): 378-388; 1977.

Anatomic, histologic, roentgenologic, and fluoroscopic examinations of 10 fetal, 10 normal adult, and 6 cirrhotic adult human livers and their vasculature confirm that the human liver consists of nine units and that the prevailing pattern of the intrahepatic vasculature of the fetal liver is a simpler form of the adult pattern. This supports the surgical technique of controlled partial hepatectomy based on preliminary ligation of the blood vessels and bile ducts connected to the segments or lobes to be resected. In portal cirrhosis, repeated destruction and regeneration of the liver parenchyma and the pressure of regenerating nodules and fibrosis result in narrowing, compression, distortion, and obliteration of the hepatic veins and, to a lesser extent, the portal veins (and hepatic arteries in the late stages). These changes also result in portal hypertension. Compensatory dilatation of the hepatic arteries in the earlier stages of portal cirrhosis maintains an adequate arterial supply to the liver parenchyma, which is separated from its portal blood supply. Increased anastomoses between hepatic arteries and portal veins allow hepatic arterial pressure to be transmitted to the venous network and contribute to the rise of portal pressure. Porta hepatic and portasystemic venous collaterals develop at several anastomotic sites, especially as esophageal varices, but they fail to relieve portal hypertension, are prone to rupture, and cause alarming hemorrhage that may be controlled by medical treatment, transesophageal ligation of varices, porta-azygos disconnection, or a selective distal splenorenal shunt. Portacaval shunts are the most effective measures against hemorrhage from portal hypertension, but they are not free from danger and, thus, should be reserved for patients with recurrent hemorrhage and weak or reversed portal flow.

7185 TRANSABDOMINAL SUTURE OF BLEEDING GASTRO-OESOPHAGEAL VARICES IN CRYPTOGENIC CIRRHOSIS OF THE LIVER.

(Eng.) Lam, S. K.; Lam, W. K. Cheng, F. C. Y.; Ong, G. B. (Univ. Hong Kong, Queen Mary Hosp., Hong Kong). *Br. J. Surg.* 64(6):428-432; 1977.

Emergency transabdominal suture of gastroesophageal varices was performed when conventional conservative measures, including esophageal tamponade, failed to control bleeding in 60/167 patients with cryptogenic cirrhosis and bleeding varices. The immediate mortality figure for the entire series was 50 patients; 26/107 who did not have surgery and 24/60 who did. Progressive liver failure accounted for 13 deaths among conservatively treated patients and 14 deaths among surgically treated patients. The transabdominal approach detected and successfully treated 19 patients who had concomitant bleeding from extraesophageal sources. Mortality in both treatment groups was directly related to the degree of liver function impairment, and it reached 100% for patients with severe (grade C) liver dysfunction, irrespective of treatment. Female patients had a significantly ($p<0.05$) lower mortality (13.3%) than males (33.6%). Increasing age was also generally correlated with mortality. Bleeding was arrested successfully in 96.7% of the surgically treated patients, and recurrence of bleeding was acceptably low (10-15%) during the first 6 months after surgery but not thereafter (about 80% recurrence of bleeding at 36 months postsurgery).

7186 BENEFITS OF VASOPRESSIN IN GASTROINTESTINAL HEMORRHAGE--FACT, FICTION, OR FANCY?

(Eng.) Wexler, M. J. (Royal Victoria Hosp., Montreal, Quebec, Canada). *Can. J. Surg.* 20(4):310-313; 1977.

Literature concerning the use of vasopressin in the control of gastrointestinal hemorrhage is reviewed. In one uncontrolled, nonrandomized, retrospective study carried out in 24 cirrhotic patients, vasopressin failed to control bleeding recurrences in many cases. The poor results in this study, however, may have been due to three factors: (a) 15 patients were bleeding only from gastric erosions, rather than esophageal varices, suggesting that some unstated preselection process led to the choice of this form of therapy; (b) vasopressin was infused into the superior mesenteric artery, rather than into the bleeding artery or the vessel more directly feeding the area of bleeding; and (c) the dosage and technique used for control and eventual cessation of therapy may not have been optimal (only 0.2 pressor U/min were used, monitored only by clinical arrest of bleeding). The effectiveness of the administered dose during infusion must be carefully and repeatedly monitored by angiography, and rates of up to 0.4 U/min may be required to achieve satisfactory and safe vasoconstriction. In the first prospective, randomized, controlled trial of vasopressin in upper gastrointestinal hemorrhage, vasopressin was significantly more effective in controlling hemorrhage than conventional therapy. In this study, 34 of the 53 patients had cirrhosis, and the results were similar for both cirrhotic and noncirrhotic patients with both variceal and nonvariceal hemorrhage. Rebleeding within 5 days of initial control occurred in 33-45% of the patients. Studies concerning the possible deleterious effects of parenteral vasopressin upon hepatic blood flow, and on the use of i.v.-administered vasopressin are discussed. The therapeutic value of vasopressin is uncertain in cirrhotic patients. It is clearly more valuable for the initial arrest of bleeding, but rebleeding is frequent. An easily applied i.v. infusion could be the primary method for vasoconstrictive therapy of massive variceal bleeding; at other sites, selective infusion into the artery more directly feeding the bleeding site is necessary.

7187 ARTERIAL HEMODYNAMICS OF THE LIVER AND SPLEEN IN PATIENTS WITH LIVER CIRRHOSIS. (Ger.) Lindenbraten, L. D.; Filimonow, G. P.; Savtschenko, A. P. (I. Moscow Medical Inst., Pirogowski St. 2/6, Moscow, USSR). *Fortschr. Roentgenstr.* 127(1):19-25; 1977.

The results of detailed angiographic studies of 111 patients with liver cirrhosis, 12 patients with thrombosis of the portal system, and 105 control subjects were compared. In the controls, the blood flow (ml/kg body weight) was 15-18 in the celiac trunk (CT), 8-10 in the splenic artery (SA), and 7-9 in the hepatic artery (HA). Values for the patient groups were: 15-20 CT, 8-11 SA, and 7-10 HA in patients with liver cirrhosis without portal hypertension (PH); 18-24 CT, 12-19 SA, and 3-5 HA in patients with cirrhosis, intrahepatic blockage, and small-caliber artery; 19-24 CT, 11-20 SA, and 8-12 HA in patients with intrahepatic blockage and normal or dilated HA; and 22-31 CT, 12-21 SA, and 10-13 HA in patients with thrombosis of the portal system (mixed blockage). Compared with controls, the diameter of the CT and SA was increased in all forms of PH, that of the common and proper HA was reduced in intrahepatic PH and increased in mixed and extrahepatic PH, and the diameter of the left gastric artery was increased in intrahepatic and mixed PH. All forms of PH were characterized by increased blood flow in the splenic and left gastric arteries. The angiographic findings confirm the existence of a close interdependence between the arterial and portal systems, systems that can be regarded as separate limbs of a common vascular chain.

7188 SPLENECTOMY AND SUBSEQUENT MORTALITY IN VETERANS OF THE 1939-45 WAR. (Eng.) Robinette, C. D.; Fraumeni, J. F., Jr. (Natl. Acad. Sciences, 2101 Constitution Ave., N.W., Washington, DC 20418). *Lancet* 2(8029):127-129; 1977.

The risk of cancer, cardiovascular disease, and other possible long-term consequences of splenectomy was assessed in 740 American servicemen splenectomized because of trauma during the 1939-45 war. There was a significant excess mortality from pneumonia and ischemic heart disease in comparison with 740 controls ($p<0.05$). Mortality from cirrhosis was also increased, but not significantly. The findings confirm that the risk of fatal infections is increased by asplenia; however, the risk of cancer was not increased, as it is in some other immunodeficiency states. Postsplenectomy thrombocytosis and hypercoagulability may account for the increased risk of fatal myocardial ischemia in this group.

7189 MITOCHONDRIAL FUNCTIONS AND CONTENT OF MICROSOMAL AND MITOCHONDRIAL CYTOCHROMES IN HUMAN CIRRHOSIS. (Eng.) Gil, J. D.; Rossi, I.; Escartin, P.; Segovia, J. M.; Gosalvez, M. (Facultad de Medicina, Universidad Autonoma, Madrid, Spain). *Clin. Sci. Mol. Med.* 52(6):599-606; 1977.

Mitochondria and microsomal fractions were isolated from the liver biopsies of eight patients with alcoholic cirrhosis, two with cryptogenic cirrhosis, two with chronic aggressive hepatitis, and six with normal livers. Normal livers yielded an average of 40 ± 4 mg of mitochondrial protein/g of tissue, cirrhotic livers 18-22 ± 1.5 mg/g. Compared with control livers, all the pathological livers showed a substantial and significant decrease ($\geq 50\%$, $p<0.005$) in the mitochondrial respiratory control ratio with glutamate + malate or succinate as substrate. The number of ADP molecules phosphorylated to ATP by the mitochondria per atom of oxygen consumed, with both substrates was slightly decreased from the control value in all but three liver disease patients. Microsomal fractions from all types of diseased liver showed a mean decrease of about 50% in cytochrome b_5 and cytochrome P-450 content compared with control livers. Apparently, cirrhotic livers yield less mitochondria than normal livers, and these mitochondria are functionally different. The fact that microsomal cytochromes were also markedly decreased, in cases of chronic aggressive hepatitis implies that this phenomenon is readily detected even in precirrhotic states.

7190 RED BLOOD CELL TRANSKETOLASE ACTIVITY IN CIRRHOSIS AND IN FULMINANT HEPATIC FAILURE. [Abstract]. (Eng.) Labadarios, D.; Roussouw, J. E.; Davis, M.; Williams, R. (Dept. Medicine, Univ. Stellenbosch, P.O. Box 63, Tygerberg 7505, South Africa). *S. Afr. J. Sci.* 73:187; 1977.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

7195 TECHNIQUE, DIFFICULTIES, AND RESULTS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP). (Ger.) Soehendra, N. (Chirurgische Universitatsklinik, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Chirurg* 48(2):98-104; 1977.

Experience with endoscopic retrograde cholangiopancreatography (ERCP) is presented on the basis of 604 cases. ERCP is a valuable tool in the diagnosis of bile duct obstruction. Premedication consists of diazepam (10 mg i.v.), atropine sulfate (0.5 mg), and hyoscine *N*-butylbromide (100 mg). The pharyngeal mucosa is anesthetized with Xylocaine spray. Liquid dimethylpolysiloxane preparations are used to prevent excessive foaming of the duodenal juice. The contrast agent used is combined with gentamycin. Lack of contrast due to air bubbles in the catheter or syringe can mimic concretions, and extreme filling may render small concretions invisible and thus lead to a false-negative. Insufficient filling may mimic pathological defects, e.g., carcinoma, especially in the area of the bifurcation or cystic duct. Of the 604 cases, the complication rate was 2%, the mortality rate 0%.

7196 TRANSHEPATIC PERCUTANEOUS CHOLANGIOGRAPHY WITH THE FINE CHIBA NEEDLE. (Fre.) Mousseau, R.; Bourgie, J. (Hopital Maisonneuve-Rosemont, 5415, boul. de l'Assomption, Montreal, Quebec H1T 2M4, Canada). *Can. Med. Assoc. J.* 117 (3):252-254; 1977.

Use of the fine Chiba needle for visualizing intrahepatic bile ducts radiographically was successful in 32/40 patients. Indications for its use were abdominal pain and/or icterus; contraindications were temperature >38 C, altered blood coagulation, or allergy to iodine. Patients were premedicated with meperidine (50 mg i.m.) and promethazine (25 mg i.m.), and placed in the dorsal decubitus position. The radiopaque substance Renographin-60 was slowly introduced into the liver by the needle under fluoroscopic control. In 18 patients the biliary ducts were dilated (diameter >6 mm) and in 14, the ducts were of normal caliber. Hepatic biopsies were performed on seven of eight patients whose ducts were not visualized, and in no case were the ducts dilated. Complications of the procedure were of brief duration or readily reversible (abdominal pain, 18; nausea and vomiting, 5; fall in blood pressure with bradycardia, 1). It is concluded that nonvisualization of the intrahepatic ducts by this method indicates the presence of nondilated ducts.

7197 CLINICAL EXPERIENCE WITH INFUSION CHOLEGRAPHY USING IOTROXAMIDE (BILISCOPIN®). (Ger.) Stillger, E.; Persigehl, M.; Frik, W. (Medizinische Fakultat an der Rheinisch-Westfalischen Technischen Hochschule, Goethestrasse 27/29, 5100 Aachen, W. Germany). *Roentgenblaetter* 30(8):414-420; 1977.

I.v. infusion cholangiocholecystography with iotroxamide (Biliscopin; 100 mg, iodine content 50 mg/ml, total iodine dose 5 mg, infusion rate 66 drops/min, infusion time 30 min) was performed in 43 patients. The indications for cholangiocholecystography were obscure upper abdominal complaints in 22 patients, cholecystitis in 7, cholelithiasis in 21, jaundice in 1, suspected tumor in 3, high ESR or fever in 2, and diagnosis before gastric surgery in 6. Adequate diagnostic evaluation of radiograms was possible in 37/43 cases, usually within 60 min. Minor subjective side-effects (pain at the infusion site, burning sensation) were seen in four patients only. Except for two patients with bile flow obstruction, serum parameters (bilirubin, alkaline phosphatase, SGOT, and SGPT) showed no significant alterations after the contrast medium was administered.

7198 PEROPERATIVE MANOMETRY OF THE BILIARY DUCTS. I. CLINICAL DATA.

(Fre.) Tsuda, Y.; Kinoshita, H.; Shiraha, Y. (Sch. Medicine, Univ. Osaka, Japan). *Lyon Chir.* 73(4):255-259; 1977.

Manometry using a modified Mallet-Guy method (intraductal pressure measured independently of cholangiography) was performed in 122 patients during surgery for gallbladder calculi (76), gallbladder polyps (2), common bile duct calculi with intrahepatic lithiasis (43), and choledochal cyst (1). A normal manometric curve was established for patients undergoing surgery for gallbladder disease who had normal hepatic tests and no evidence of hepatic, pancreatic, or biliary duct disease on exploration. Abnormal curves (ascending phase 30 sec with or without a prolonged descending phase) were obtained in 22/78 patients with calculi or polyps of the gallbladder and in 43/43 with calculi of the common duct. Prolongation of the descending and ascending portions of the curve was more likely to occur with the latter patients (34/43). Diagnostic accuracy was raised to 92.4% after peroperative manometry and to 99% when cholangiography was also performed.

7199 REFLUX INTO THE PANCREATIC DUCT DURING PEROPERATIVE BILIARY RADIOMANOMETRY. REPORT OF 200 CASES.

(Fre.) Lataste, J.; Albou, J. C. (Centre Hospitalier Intercommunal, 40, avenue de Verdun, 94000 Creteil, France). *J. Chir. (Paris)* 113(1):3-14; 1977.

Two types of reflux into the pancreatic duct were detected by radiomanometry during biliary operations in 200/2,500 patients. Functional reflux (I), which occurred in 109 patients, was due to a common duct with or without an ampulla of Vater or to an isolated duodenal obstruction. Secondary reflux (II), which occurred in 38 patients, was due to a pathological obstruction (impacted gallstones, odditis) below the choledocho-Wirsung crossway. No anatomical, organic, or physiological cause for reflux was found in 53 patients. Overall, 28/109 patients with reflux I had odditis, but it disappeared after sphincterotomy. There was no correlation between degree of reflux and choledochal perfusion pressure. The chronological order of reflux partly depended on its nature. Early reflux was found mainly in reflux II, but reflux secondary to passage into the duodenum was found in reflux I. Wirsung's duct was dilated five times more frequently in reflux II patients than in reflux I patients. Santorini's duct was opacified in 26 patients: 10 with reflux I and 10 with reflux II; in 6 the cause was not known. In 17 patients, the reflux flowed into the duodenum. Thus, reflux into Santorini's duct was three times more common in cases of papillary obstruction. No specific surgery is needed in most cases of reflux into Wirsung's duct when it is purely functional or due to an unknown cause. However, in pathological cases accompanied by dilatation of the duct, sphincterotomy should be performed.

7200 EARLY OR INTERVAL CHOLECYSTECTOMY: MORPHOLOGIC AND BACTERIOLOGIC FINDINGS.

(Ger.) Meier zu Eissen, P.; Fuchs, C. G.; Hirsch, H. C. (Kreiskrankenhaus Herford, Auf dem Dudel, 4900 Herford, W. Germany). *Aktuel. Chir.* 12(4):255-262; 1977.

The bacteriological and morphological characteristics of 32 patients who underwent early cholecystectomy (1-4 days after the onset of acute cholecystitis) and 111 patients who underwent interval cholecystectomy (6-9 weeks after onset) were studied. Fifty-eight patients in the interval cholecystectomy group received antibiotic therapy (tetracycline) for 5-6 weeks before surgery. Postoperative mortality was 1/32 and 2/111 patients, resp. Bacteriological tests of the bile were positive in 11/32 and 32/111 cases; i.e., there was no significant difference between the two groups in spite of the fact that many interval cholecystectomy patients received antibiotic treatment. Liver biopsy specimens showed pathological changes in 27/32 and 83/111 cases. These findings show that the reservations against early cholecystectomy for acute cholecystitis are not justified and that early cholecystectomy should be performed whenever possible.

7201 ENDOSCOPIC PAPILLOTOMY.

(Eng.) Seifert, E.; May, B. (Medical Sch. Hannover, Hannover, W. Germany). *Acta Gastroenterol. Belg.* 40(1/2):31-40; 1977.

Endoscopic papillotomy was used to treat 10 patients for the following reasons: remaining stones in the common bile duct after cholecystectomy (3 cases); stenosis of the papilla of Vater or of the choledochian sphincter (4); and choledochus stump syndrome in which there is encrusted material in the bile duct near the papilla, resulting in recurrent cholangitis (3). A specifically designed duodenoscope, which is easy to insert through the pyloric ring and can be placed near the papilla of Vater, was used. After cannulation of the papilla and injection of dye into the common bile duct, the cannulation tube was removed, and a specially designed papillotoma was inserted through the papilla into the common bile duct. A 1-cm incision was made in the upper part of the papilla after the open stoma was visualized and the cannula was reinserted to record the function and outflow of the stoma. Stools of the patients with remaining stones in the common bile duct were examined for 3 days for spontaneous delivery of the calculi. If all of the stones were not passed, duodenoscopy was performed again, and the common bile duct was cannulated and filled once more with dye to visualize the remaining gallstones. These were then extracted with a Dormia basket. The same procedure was performed in the choledochus stump syndrome, if encrusted material remained in the bile duct system after choledochoduodenostomy. Either spontaneous delivery or stone removal with a Dormia basket was successful in the three cases of remaining stones after cholecystectomy. Open papillotomy was successful in the four cases of papillary stenosis and in the three cases of choledochus stump syndrome. The procedure should be limited to older patients who are poor surgical risks.

7202 MICRO-ORGANISMS IN THE BILE: A PREVENTABLE CAUSE OF SEPSIS AFTER BILIARY SURGERY.

(Eng.) Keighley, M. R. B. (Univ. Birmingham, Birmingham, England). *Ann. R. Coll. Surg. Engl.* 59(4): 328-334; 1977.

The use of preoperative antibiotic treatment to reduce morbidity after biliary surgery in patients with infected bile is reported. Biliary infection was found in 57/181 patients undergoing biliary surgery. The majority of the organisms (87%) were aerobic bacteria, particularly *Escherichia coli*, *Streptococcus faecalis*, and *Klebsiella aerogenes*. An analysis of 282 patients revealed that when organisms were found in the bile at operation, the incidence of wound sepsis (38%) and septicemia (16%) was significantly greater than in patients with sterile bile (10% and 5%, resp.). After choledochotomy, wound infection and septicemia were significantly more common in patients with bacteria in the T-tube drain (45% and 22%, resp.) than in patients in whom the bile remained sterile throughout the drainage period (7% and 0%, resp.). Gram-negative aerobic organisms were uniformly sensitive to gentamicin. Gram-positive aerobic bacteria and anaerobic bacteria were resistant to this antibiotic and all but two of these organisms were resistant to ampicillin. When the effects of gentamicin (80 mg/dose, i.m.) or rifamide (150 mg/dose, i.m.) therapy were evaluated in 150 consecutive patients, a significant ($p<0.05$) reduction in wound sepsis (6% versus 22% for controls) and septicemia (2% versus 14% for controls) was demonstrated only in patients receiving gentamicin. Unlike gentamicin, serum levels of rifamide were inadequate. The only patients who benefited from antibiotic cover were those in whom the bile was infected at the time of operation. Patients with infected bile can be identified by preoperative duodenal aspiration, operative Gram staining of bile, or by analysis of the clinical presentation and operative findings. High-risk patients requiring preoperative antibiotic therapy include those >70 yr of age, jaundiced patients, those requiring emergency operation, patients with recent rigors, those with previous biliary operations, and patients known to have choledocholithiasis. Preoperative antibiotic treatment is concluded to reduce biliary operation morbidity.

7203 PRIMARY CARCINOMA OF THE GALLBLADDER.

(Fre.) Henry, X.; de Lestang-Labrousse, M.; Stoppa, R.; Banti, B. (Clinique chirurgicale universitaire, C.H.U., place V. Pauchet, 80030 Amiens, France). *J. Chir. (Paris)* 113(4):383-394; 1977.

Twenty-four cases of primary carcinoma of the gallbladder were analyzed and compared with those reported in the literature. This group was among 875 patients operated for gallbladder disease. Cholelithiasis seemed to be a predisposing factor, and it was present in 18 patients. Macroscopically, the carcinoma was localized in 1 patient, confined in 2, and of a hepatovesicular form in 21. Histologically, 15 were well-differentiated adenocarcinomas, 4 mucosecreting glandular epitheliomas, 2 epidermoid epitheliomas, and 1, an unknown type. Similar to the literature cases, the lymph system was also affected. Hepatic involvement was seen in 21 patients, and hepatic metastases in 8. Other affected organs included the bile duct (25%), pancreas (11%), stomach (9.5%), duodenum (8%), colon (5%), and abdomen (2.5%). The main symptoms were pain, emaciation, fever, icterus, nausea and vomiting, constipation, and external and digestive hemorrhaging. Eight patients had elevated alkaline phosphatase levels associated with a disturbance of BSP retention. Radiological examinations gave indefinite results. Eight p.o. cholecystographies and 10 i.v. cholangiographies were performed; the latter showed the absence of bladder opacification (8) and normal bile ducts (5). Gastrointestinal transit revealed compression of the bulb (4) and antrum (2) and filling of the large gastric curve (1). Overall, there is no diagnostic method of choice. The preferred surgical procedure is cholecystectomy with or without hepatic resection or lymphatic curettage. Four of the 24 patients benefitted from this procedure, with 1 surviving 6 yr and 3 surviving 9, 4, and 3 months, resp. Due to a poor prognosis of this carcinoma, the following pathological classification has been suggested: 0, I, II, II a and b, and IV a and b, in relation to tumor spread. Cholecystectomy seems to be the best method for preventing bladder carcinoma in any case of cholelithiasis without contraindications.

7204 SURGICAL PROBLEMS IN PRIMARY SCLEROSING CHOLANGITIS.

(Eng.) Salembier, Y. (69, rue de la Louviere, 59000-Lille, France). *Int. Surg.* 62(6/7):328-331; 1977.

The cases of five patients with sclerosing cholangitis are presented. The cases of the first two patients, women aged 21 and 22 yr, illustrated the typical evolution of the disease. The level of jaundice varied initially but finally ended in a continuous biliary retention. Their symptoms also included pruritus and attacks of cholangiolitis. The clinical picture in both patients was that of obstructive jaundice. Duodenoscopy and retrograde cholangiography showed narrowed and irregular bile ducts. The patients developed cirrhosis and died after episodes of gastrointestinal bleeding or colitis, 15 and 11 yr, resp., after the initial symptoms appeared. Radiology revealed an abnormal bile duct in one patient and a strictured, moniliform bile duct in the other. The segmentary interlobular bile ducts were surrounded by rings of fibrosis, resulting in chronic obstruction of the cholangioles. The remaining three cases illustrated difficulties encountered in the diagnosis of sclerosing cholangitis. In one of these patients, symptoms of stenosis were present, and no stones were found in the gallbladder. The symptoms recurred after cholecystectomy, and a second operation revealed severe pediculitis constricting the biliary duct with stones in dilated intrahepatic ducts. The diagnosis of another patient was complicated by the development of bile duct carcinoma. The last patient had cholangiolitis with pericholangiolitis, and xanthomatosis, features typical of primary biliary cirrhosis; the differential diagnosis between primary biliary cirrhosis and sclerosing cholangitis was difficult. Histologic studies, the presence of cholangiolitis, and obstructive pericholangiolitis indicated the correct diagnosis.

7205 UNDETECTED CHOLEDOCHOLITH. (Ger.) Schmidt, H. D. (Chirurgische Univ.-Klinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Z. Gastroenterol.* 15(2):106-118; 1977.

Reintervention for undetected choledocholith was necessary in 81/3,618 patients operated on for cholelithiasis of the extrahepatic bile ducts. Papillary stenosis was found in 16/81 cases. Cholangitis was diagnosed in 30 patients, and only 10 had no history of jaundice. In most cases, the first intervention consisted of cholecystectomy. The interval between the onset of symptoms and first intervention averaged 20 months, ranging from a few days to 34 yr. Residual calculi were detected by i.v. cholangiography, cholangiotomography, or percutaneous transhepatic cholangiography. Reintervention consisted of bougienage of the papilla with primary closure (46 cases), T drainage (14), papillotomy (2), elimination of the biliodigestive anastomosis (7), second resection of the cystic duct stump (7), and hepaticojejunostomy (5). Litholysis with chenodeoxycholic acid was unsuccessful in two patients, and both were subsequently reoperated. Postoperative complications included pancreatitis (1 case), purulent peritonitis (3), pneumonia (3), and healing by second intention (8). Postoperative mortality was 4.9% for all 81 patients and 2.4% for those with choledocholith without stricture. The findings indicate that in view of the lack of experience with chemical litholysis, endoscopic papillotomy and mechanical extraction surgery are the methods of choice for undetected choledocholith.

7206 FREQUENCY OF GALLSTONE DISEASE IN A WELL-DEFINED SWEDISH POPULATION: A PROSPECTIVE NECROPSY STUDY IN MALMO. (Eng.) Lindstrom, C. G. (Univ. Lund, General Hosp., Malmo, Sweden). *Scand. J. Gastroenterol.* 12(3):341-346; 1977.

The frequency of gallstone disease (gallstone at necropsy or postoperative state of gallstone disease) in unselected necropsy material consisting of 2,218 subjects from Malmo, Sweden was 44% (368 men, 607 women). Gallstones were found in 306 of the men and in 498 of the women. The stones were situated in the gallbladder in 763, the common bile duct in 100, the cystic duct in 48, the hepatic duct in 15, intrahepatically in 5, and within the intestine in 1 case. Of 763 subjects with cholecystolithiasis, 203 had 1 stone, 275 had 2-10 stones, 135 had 11-30 stones, 83 had 31-100 stones, and 63 had >100 stones. Among 192 patients who had undergone surgery (usually cholecystectomy) for gallstones, 21 had residual gallstones in the remaining bile ducts after surgery. Chronic cholecystitis was found in 16.6% of the subjects. Cancer of the gallbladder was seen in 20 subjects, cancer of the bile ducts in 12. Gallstone disease was the immediate or contributory cause of death in 31 subjects.

7207 PRIMARY INTRAHEPATIC GALLSTONES. (Eng.) Pridgen, J. E., Jr.; Aust, J. B.; McInnis, W. D. (Univ. Texas at San Antonio, Health Science Center, 7703 Floyd Curl Dr., San Antonio, TX 78284). *Arch. Surg.* 112(9):1037-1043; 1977.

Five new cases of Caroli's disease are reported. The disease is characterized by congenital segmental dilation of the intrahepatic bile ducts, which produces a variety of symptoms and, usually, primary intrahepatic gallstones. The diagnoses were made by intrahepatic cholangiography and confirmed by a surgical specimen of the left lobe of the liver in patients 1 and 2, autopsy in 3, and an intrahepatic cholangiogram in 4 and 5. A left-sided lobectomy of the liver was performed in patients 1 and 2. Cholecystectomy, removal of common duct stones, and choledochoduodenostomy or, preferably, Roux-en-Y choledochojejunostomy were performed in patients 3, 4, and 5. Patients 1 and 3 died > 5 yr after their original surgery; patients 2, 4, and 5 are alive at 6 yr, 13 yr, and 7 months, resp., after treatment. This is a more encouraging prognosis than that usually reported in the literature.

7208 EXTRAHEPATIC BILIARY LITHIASIS IN CHILDREN. RESULTS OF A SURVEY OF 100 CASES FROM SEVERAL MEDICAL CENTERS. (Fre.) Battin, J.; Auzerie, J.; Fortier-Beaulieu, M.; Mage, K. (Hopital des Enfants, 168 cours de l'Argonne, 33077 Bordeaux Cedex, France). *Med. Infant. (Paris)* 83(5):537-557; 1976.

A series of 100 children with extrahepatic biliary lithiasis was studied. The main symptoms were acute abdominal pain, vomiting, diarrhea, and icterus. The lithiasis was discovered preoperatively in 84% of the children, by simple abdominal radiography in 59%, and by specific biliary opacification in 25%. Treatment was usually surgical, and the results were generally favorable. There was only one fatality. The etiology of the lithiasis was traceable in 50% of the children (this is usually possible in only 10% of adults). Hemolytic anemias were responsible in 24 cases, hepatic abnormalities in 5, calcemic bile in 1, biliary duct malformation in 11, and ileal resections and other intestinal malabsorption syndromes in 9. Children with primitive lithiasis showed frequent hereditary or ethnic predispositions.

Since 64% of calculi in children are radiopaque, all children with suspicious symptoms should undergo simple abdominal x-ray examinations followed by, if necessary, p.o. opacification of the biliary tree. Venous opacification should not be performed routinely.

7209 SYMPTOMATOLOGY OF LITHIASIS OF THE COMMON BILE DUCT.

(Fre.) Martin, D. (No affiliation given). *J. Med. Lyon* 57(1306):593-596; 1976.

The symptomatology and diagnosis of common bile duct lithiasis are presented based on the data of 148 case records. Overall, 65% of the cases occurred in women, and most of the patients were ≥60 yr old. Obesity (both sexes) and multiparity were also predisposing factors. There was a family history of biliary lithiasis in 10% of the patients, and 14% had had a prior cholecystectomy, which indicates that this procedure did not afford total prophylaxis. Clinical symptoms included epigastric or hypochondrial pain (88%), icterus (77%), fever (75%), shivers (45%), pruritus (30%), vomiting (25%), and emaciation (25%). Only 2.8% of the patients had a distended bladder. Biological tests revealed generally elevated conjugated bilirubin and alkaline phosphatase levels. Contrast radiography was used in 62% of the patients (icterus prevented its use in the others), and it confirmed the diagnosis in 40% of those tested. An abnormal bile duct was seen in 60%. No radiological abnormalities of the bile duct were seen in 1% of the patients. The mortality rate of the operated patients was 2.7%, compared with 19% of the unoperated patients. The latter died of angiocholitis (9%), peritoneal perforation (3%), and cardiorespiratory insufficiency (7%).

7210 65 REINTERVENTIONS FOR POSTCHOLECYSTECTOMY COMMON DUCT GALLSTONES.

(Fre.) Mallet-Guy, P. (No affiliation given). *Lyon Chir.* 73(3):176-183; 1977.

In the period 1942-1974, 311/1,272 operations for calculi of the principal biliary system were performed for recurrent or overlooked calculi. Sixty-five of these reinterventions, all in patients who had cholecystectomies with simple extirpation of the gallbladder but without exploration of the common bile duct were analyzed. In 59/65 patients, the primary biliary surgery had been performed without peroperative radiologic and manometric controls, and the bile duct stones had probably been overlooked. In the other six reinterventions, the stones were believed to be recurrent, since peroperative controls and functional signs, history, and radiographs prior to initial surgery were negative for common duct calculi. The presence of common bile duct calculi was manifested by the development of postoperative biliary fistulas in 4 patients, by nonspecific pain or weight loss in 20, and by recurring biliary crisis with icterus and fever in 41. I.v. cholangiography does not always reveal the stones. Reintervention was always performed under radiologic and manometric controls for precise location of the calculi; in 31/65 patients, a choledochoduodenostomy was performed. Four of the 20 patients operated between 1943 and 1952 died, but no deaths have occurred in the 45 operated since 1952. Only 9/53 patients followed-up required further surgery.

7211 PROBLEMS OF CHOLECYSTECTOMY FOR LITHIASIS. ANALYSES OF STATISTICS FOR 1,000 CASES.

(Fre.) Devic, G.; Debouvry, J.; Garde, J. (46 bld de la Republique, F 38200 Vienna, Austria). *Lyon Chir.* 73(3):170-175; 1977.

From 1964 to 1976, cholecystectomies were performed in 1,000 patients with lithiasis of the common bile duct by similar methods with the exception that peroperative radiological and manometric controls were not used in 57 patients (emergency surgery, catheterization difficult or inadvisable). The average age of the 150 men and 850 women was 52 and 45 yr, resp. Obesity was present in 13.6% (weight >30% of ideal), hypertension in 8.7%, histological alterations in the liver in 40% (usually not serious), and acute pancreatitis in 27 patients. There were 10 deaths, all patients with acute cholecystitis. Complications were most likely to occur in patients >60 yr old, in those treated medically for >8 days, and in those with acute cholecystitis. They included postoperative infections in 45, evisceration in 4, and peroperative injury of the biliary pedicle in 6 (2 arterial, 2 of a healthy duct, and 2 of involved duct). Sixty-four patients had symptomless calculi of the common duct, and in 62 the calculi were discovered at surgery by exploration or radiographs. Diagnosis and treatment of anatomical or functional biliary stasis, compression of the common duct by the pancreatic nodules, and fibrosis of the sphincter of Oddi are also discussed.

7212 DESATURATION OF BILE AND CHOLESTEROL GALLSTONE DISSOLUTION WITH CHENODEOXYCHOLIC ACID.

(Eng.) Hofmann, A. F. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Am. J. Clin. Nutr.* 30(6):993-1000; 1977.

The use of chenodeoxycholic acid for the desaturation of bile and the dissolution of cholesterol gallstones is discussed. When chenodeoxycholic acid comprises >70% of the biliary bile acids, the amount of cholesterol secreted in bile falls, and the bile becomes cholesterol unsaturated. If cholesterol gallstones are present and they are exposed to this unsaturated bile, they will dissolve in 4-24 months in most patients. The effective p.o. dose of chenodeoxycholic acid for gallstone patients appears to be 12-15 mg/kg, even in nonobese patients. This range is successful in 50-70% of the patients. Extensive clinical experience indicates that chenodeoxycholic acid therapy is safe in humans, despite unequivocal toxicity in several nonhuman primates. When chenodeoxycholic acid therapy is stopped, the bile becomes resaturated and stones may recur. When gallstones do recur, they respond promptly to chenodeoxycholic acid, but the optimal mode of management for patients with recurrent stones after a previous successful medical treatment has not yet been defined. Since cholecystectomy is a rapid, safe, effective, and usually permanent treatment for all gallstones, the value of medical therapy with chenodeoxycholic acid is uncertain at present, except for patients in whom surgery is inadvisable.

7213 CHOLELITHOLYTIC ACTION OF CHENODEOXYCHOLIC ACID WITH LONG-TERM TREATMENT. (Ita.)

Mereto, G. C. (Servizio di Anestesia e Rianimazione, Ospedali Civili di Genova, Genoa, Italy). *Minerva Gastroenterol.* 22(2):168-172; 1976.

Sixteen patients with radiotransparent gallstones were treated with chenodeoxycholic acid on a 4-day on, 3-day-off regimen of 0.75-1.0 g/day. Five patients were treated for ≥6 months and 11 for 3-4 months. There were no drug-related increases in SGOT, alkaline phosphatase, or bilirubin in any of the patients after 3 months of treatment. Five of the 11 patients treated for 3-4 months showed no radiologic changes in their gallstones. However, the stones disappeared in two patients treated for 6 months, and they were greatly reduced in two others. The two patients whose stones disappeared were put on maintenance therapy of 0.5 g/day on alternate weeks, and the stones did not reappear. There were no adverse reactions to treatment, except for a mild diarrhea in six patients that was controlled by adjusting the dosage. Most patients reported subjective improvement of symptoms, especially digestive difficulties. Chenodeoxycholic acid appears to be an effective treatment for gallstones.

7214 PLASMA ENZYMES IN THE DIFFERENTIAL DIAGNOSIS OF CHOLESTATIC SYNDROMES. (Ger.)

Klein, U. E. (Abteilung fur Allgemeine Innere Medizin, Zentrum Konservative Medizin I der Universitat, Schittenhelmstrasse 12, D-2300 Kiel, W. Germany). *Med. Klin.* 72(9):337-342; 1977.

Studies of the diagnostic significance of plasma alkaline phosphatase (AP) levels are reviewed. Concurrent changes in the total AP and liver AP (LAP) activities indicate a hepatic origin of disease, but an isolated increase of enzyme activity indicates that it has an osseous origin. There is a significant positive correlation between AP and LAP activities ($r=+0.662$, $p<0.001$) in normal subjects. An increased AP level against the background of a normal LAP level indicates skeletal disease, but an increased LAP level without an increased AP level may indicate a long-standing obstruction syndrome. The increase in AP and LAP activities that is frequently observed during pregnancy is hepatogenic only when there is a simultaneous rise in γ-glutamyltranspeptidase activity.

7215 CHOLESTASIS IN PREGNANCY. (Fre.)

Merger, C.; Chadeyron, P. A.; Levy, J. (Cheverny III, 122, rue du Commandant Rolland, F 13008, Marseille, France). *J. Gynecol. Obstet. Biol. Reprod. (Paris)* 6(3):357-366; 1977.

The diagnosis and characteristics of cholestasis in 20 pregnant women are presented. Pruritus was observed in 18 patients; in 2 it was preceded by conjunctival subicterus and in 1 by vomiting. Icterus occurred in 11 patients between 30-35 weeks of pregnancy; hepatomegaly was noted in 3. Treatment with cholestyramine was effective in 6/13 patients. Laboratory examinations revealed frank biliary retention in all patients. Total bilirubin level ranged from 12 to 45 mg; alkaline phosphatase levels were consistently elevated (90-190 IU); and total cholesterol levels ranged from 2.6 to 5.6 g. Although cytolysis was noted in all patients, it was never marked, and hepatocellular function was normal. However, all patients had abnormal BSP-clearance tests. Four patients had twin pregnancies, which suggests that there may be a relationship between twin pregnancies and cholestasis. Maternal prognosis was good except in one patient in whom hemorrhage during delivery was accompanied by hypoprothrombinemia. In contrast, only four infants reached full term; the remainder were born prematurely. Pregnancy was prolonged 1-5 weeks in six patients by a β-mimetic tocolytic agent (Ritodrine). The amniotic fluid was discolored in nine patients. Fetal cardiac rhythm was often bradycardiac. Of the 25 infants born, 4 died (3/4 were twins). Most infants had an Apgar score of 7-9 in the first minute, 9-10 in the fifth minute. Arterial blood pH at birth was mostly low. Anemia was present in 10/21 surviving infants and 13 had neonatal icterus. Cholestasis of pregnancy is frequently associated with twin pregnancy and the prognosis for the fetus is especially affected by prematurity. β-Mimetic drugs are useful for the treatment of threatened premature labor and are of no danger to the mother.

7216 IATROGENIC BILE DUCT LESIONS. (Ger.)

Ehlert, C. P.; Schmidt, H. D. (Allgemeinchirurg. Klinik, Nordwestkrankenhauses Sanderbusch, D-2945 Sande, W. Germany). *Z. Gastroenterol.* 15(2): 119-125; 1977.

General clinical, diagnostic, and therapeutic aspects of iatrogenic lesions of the extrahepatic bile ducts are discussed on the basis of 31 cases that occurred following surgery on these structures. The lesion is usually caused by squeezing, tangential injury, or total dissection. Biliary fistula and bile duct stenosis are possible consequences of iatrogenic lesions. With serum bilirubin levels of up to 5 mg% and an intact liver parenchyma, i.v. infusion cholangiography is usually sufficient for diagnosing the lesions. Percutaneous transhepatic cholangiography is indicated only at serum bilirubin levels >5 mg%. Local intervention, e.g., suture of a leak, removal of ligation, or end-to-end anastomosis of a dissected duct, is possible only if the lesion is discovered intraoperatively. Lesions discovered later require biliodigestive anastomosis or, if no extrahepatic duct is available for the anastomosis, hepaticocholangioenterostomy. Partial liver resection with subsequent reconstruction of the stenosing duct is reserved for cases of cholangitis that have led to liver abscess. The biliodigestive anastomosis should be in the form of a hepaticojejunostomy in view of the considerable risk of stenosis.

7217 MALIGNANT OBSTRUCTIVE JAUNDICE. CURRENT STATUS OF SURGICAL MANAGEMENT.

(Ger.) Schmidt, H. D.; Ruckert, R.; Brunner, H. (Chirurgische Univ.-Klinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Z. Gastroenterol.* 15(2):89-98; 1977.

Preliminary results of the surgical treatment of 424 patients with obstructive jaundice due to malignant tumors are presented. Carcinomas of the gallbladder (84 cases), bile ducts (68), papilla (25), and head of the pancreas (247), were diagnosed. Among the 152 patients with bile duct and gallbladder carcinomas, the carcinoma was limited to the organ in 12 cases only; 78 patients had regional lymph node metastases, and 62 had distant metastases. Exploratory laparotomy was performed in 101 cases, cholecystectomy in 21, extended cholecystectomy in 3, biliodigestive anastomosis in 2, and tumor bougienage with a T drain in 23. The average survival time was 6 months. Only 60/272 patients with carcinoma of the head of the pancreas and papilla were operable; partial duodenopancreatectomy was performed in 54 cases and total duodenopancreatectomy in 6. Postoperative mortality was 18%. The other patients underwent palliative surgery (gastroenteral anastomosis) and their average survival time was 6 months.

7218 CYSTADENOMA OF THE BILE DUCT AS THE CAUSE OF RECURRENT OBSTRUCTIVE JAUNDICE.

(Ger.) Gronniger, J.; Ruckert, K.; Seitz, W. (Chirurgische Univ.-Klinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Z. Gastroenterol.* 15(2):99-105; 1977.

Two cases of long-standing intermittent obstructive jaundice due to benign bile duct tumor (cystadenoma) are reported. A 30-yr-old woman developed intermittent jaundice during the first 3 yr after cholecystectomy. A cholecystogram was negative at that time. Choledochotomy was performed 12 yr after the first surgery with the tentative diagnosis of extrahepatic obstruction due to a postoperative adhesion tumor. A pedunculated, partly cystic, partly solid intraductal tumor was found in the resected common bile duct. The patient is now symptom-free 1 yr after surgery. A 50-yr-old woman who underwent cholecystectomy for cholelithiasis 7 yr previously developed intermittent obstructive jaundice 1 yr later. A pedunculated cystadenoma of the common bile duct was removed at exploratory laparotomy. The patient remains symptom-free after surgery. The findings indicate that benign bile duct tumors should be considered a possible cause of recurrent intermittent obstructive jaundice.

7219 CONTRALATERAL DISPLACEMENT OF ABDOMINAL VISCERA BY A RETROPERITONEAL LIPOSARCOMA: ULTRASONIC DEMONSTRATION.

(Eng.) Kim, E.; Goldman, S. M.; Minkin, S. D.; Salik, J. O. (Sinai Hosp. Baltimore, Inc., Belvedere at Greenspring Ave., Baltimore, MD 21215). *J. Clin. Ultrasound* 5(2):117-120; 1977.

The case of a patient with contralateral displacement of the kidney, gallbladder, and liver by an encapsulated, well-differentiated, low-grade liposarcoma is presented. The patient, a 27-yr-old woman, presented with a right upper quadrant mass, 2 months after the delivery of a normal child. An abdominal ultrasound examination demonstrated a large, complex mass in the right upper quadrant extending at least to the midline. The right kidney, easily identified because of its characteristic sonographic appearance, was displaced to the midline. The bulk of the liver appeared to lie more to the left than is normally seen. The gallbladder was immediately to the left of the liver. An i.v. pyelogram and a p.o. cholecystogram confirmed the displacement of the kidney and gallbladder, resp., and an upper gastrointestinal series, barium enema, and liver scan confirmed the size and location of a large right-sided retroperitoneal mass. A large liposarcoma was found and removed at exploratory surgery. The tumor extended from just below the right hemidiaphragm, posterior to the liver, and crossed the midline. This is the first case in which not only the ipsilateral kidney but also the liver and gallbladder were pushed contralaterally by a large tumor. Because benign or slowly growing malignancies allow time for the normal intraabdominal organs to "wander" from their usual anatomical positions, the ultrasonographer must be alerted to the possibility of mass lesions displacing these organs across the midline.

7220 SPONTANEOUS PERFORATION OF BILE DUCTS.

(Eng.) Donald, J. W.; Ozment, E. D., Jr. (192 Louiselle St., Mobile, AL 36607). *Am. Surg.* 43(8):524-527; 1977.

The cases of two patients with spontaneous perforation of the bile ducts are presented. In the first patient, a 67-yr-old woman, the perforation occurred in the distal common hepatic duct. Laparotomy revealed severe acute cholecystitis and cholelithiasis, and a large amount of bile-stained and cloudy fluid was seen in the peritoneal cavity. The perforation occurred in the anterior wall of the common hepatic duct near the apparent junction with the cystic duct. After the gallbladder was removed, the cystic duct was found to have a common wall with the common hepatic duct for a distance of 3.0 cm. An impacted stone was removed from the distal end of the cystic duct at the point of entry into the common duct; the perforation was approximately 1 cm proximal to this point. The common duct contained purulent bile and some thick sediment, but no definite stone was found in the common duct. In the second patient, an 87-yr-old woman, the perforation occurred in an anomalous branch of a small superficial hepatic duct. Laparotomy revealed a large amount of free bile and purulent material in the peritoneal cavity. The gallbladder was distended, acutely inflamed, and contained many stones. The perforation occurred in a small superficial biliary radical on the inferior surface of the liver; the anomalous duct radical was ligated. The common duct and hepatic ducts contained stones. The authors conclude that choledochal calculi associated with infected bile and increased pressure in the proximal ductal system are the most common etiological factors in spontaneous perforation of biliary ducts. Free bile or bile-stained fluid in the peritoneal cavity with an intact gallbladder should alert the surgeon to the possibility of bile duct perforation.

GENERAL

Regional Enteritis

7275 TREATMENT OF CROHN'S DISEASE BY LEVAMISOLE (STUDY OF 10 CASES). (Fre.) Bertrand, J.; Renoux, G.; Vandooren, M. (Service de Medecine D, CHR, 2, bd Tonnelle, 37043 Tours Cedex, France). *Ann. Gastroenterol. Hepatol. (Paris)* 13(4):361-366; 1977.

Ten patients with Crohn's disease localized in the ileum were treated with levamisole (150 mg, 3 times/week for 8-30 months). Favorable clinical improvement was noted in four of six active cases of Crohn's disease: one showed radiological improvement, and three had a stabilization of disease. The disease worsened in the other two patients, but one showed improvement for 1 yr before failure occurred. Four patients with inactive disease had no recurrence after 24, 18, 18, and 10 months, resp. Immunological tests showed constant improvement in nine of the patients. Side-effects, which included insomnia, nervousness, malaise, palpitations, and drunkenness, developed in five patients, but they did not cause termination of therapy.

7276 CROHN'S DISEASE IN CHILDHOOD. (Eng.) O'Donoghue, D. P.; Dawson, A. M. (St. Bartholomew's Hosp., London EC1A 7BE, England). *Arch. Dis. Child.* 52(8):627-632; 1977.

Clinical experience with 32 patients with Crohn's disease that started in childhood (before the age of 16) is presented. Abdominal pain, diarrhea, and weight loss were the most frequent presenting symptoms, occurring in 21, 18, and 13 patients, resp. However, unexplained fever was a presenting symptom in seven patients and was the dominant symptom in two patients; growth retardation was a presenting symptom in six patients and was the dominant symptom in two patients. Stunted growth was the most frequent physical abnormality when patients were first seen at the hospital, occurring in nine cases. Only six patients were correctly diagnosed after the initial series of investigations, and the mean delay in diagnosis was 2.9 yr. This delay was principally caused by a failure to consider the diagnosis and thus, to perform a barium follow-up examination. Diffuse disease (combined discontinuous small and large bowel involvement) was seen in 13 of the 32 patients. Large bowel involvement alone was observed in seven patients, and isolated small bowel disease was seen in only four patients. By 6 yr, 81% of the 32 patients had experienced a primary relapse (median relapse time, 17 months); of these patients, 73% experienced a further recurrence at 6 yr, with a median relapse time of 27 months. The recurrence rates at 6 yr for medically and surgically induced remissions were 85 and 61%, resp., with median relapse times of 16 and 48 months, resp. Because the MRT is much longer for surgically treated patients, surgery is recommended at an early stage of the disease.

7277 THE DILEMMA OF CROHN'S DISEASE: CROHN'S DISEASE AND APPENDECTOMY. (Eng.) Kovalcik, P.; Simstein, L.; Weiss, M.; Mullen, J. (Naval Regional Medical Center, Box 693, Portsmouth, VA 23708). *Dis. Colon Rectum* 20(5):377-380; 1977.

7278 CARCINOMA OF THE ILEUM IN REGIONAL ILEITIS. (Eng.) Gude, H. E. (No affiliation given). *J. Iowa Med. Soc.* 67(8):324-325; 1977.

7279 ROTAVIRUS ANTIBODIES IN CROHN'S DISEASE AND ULCERATIVE COLITIS [Letter to Editor]. (Eng.) De Groote, G.; Desmyter, J.; Vantrappen, G.; Phillips, C. A. (Viral Diseases Lab., Rega Inst., Univ. Leuven, B-3000 Leuven, Belgium). *Lancet* 1(8024):1263-1264; 1977.

7280 ION PAIR EXTRACTION TECHNIQUE WITH AZURE A, FOR DIFFERENTIATING BILES OF NORMAL SUBJECTS AND PATIENTS WITH LIVER DISEASE FROM PATIENTS WITH CROHN'S DISEASE WITH SMALL BOWEL INVOLVEMENT. (Eng.) Webb, G. B.; Macdonald, I. A.; Williams, C. N. (Dept. Medicine, Dalhousie Univ., 5849 University Ave., Halifax, Nova Scotia, Canada). *Clin. Chem.* 23(3):460-463; 1977.

7281 PRIMARY ACQUIRED HYPOGAMMAGLOBULINEMIA AND REGIONAL ENTERITIS. (Eng.) Fillit, H.; Bernstein, L.; Davidson, M.; Brandt, L.; Bezahler, G.; Cohen, M. (Beth Israel Hosp., New York, NY). *Arch. Intern. Med.* 137(9):1252-1254; 1977.

7282 MILD OR BITTER. (Eng.) Dawson, J. (No affiliation given). *Br. Med. J.* 2(6089):761; 1977.

7283 BIOAVAILABILITY OF METRONIDAZOLE IN FASTING AND NON-FASTING HEALTHY SUBJECTS AND IN PATIENTS WITH CROHN'S DISEASE. (Eng.) Melander, A.; Kahlmeter, G.; Kamme, C.; Ursing, B. (Univ. Hosp., EA-Blocket, S-221 85 Lund, Sweden). *Eur. J. Clin. Pharmacol.* 12(1):69-72; 1977.

7284 BREAKFAST AND CROHN'S DISEASE [Letter to Editor]. (Eng.) Gardner, M. J.; James, A. H. (Southampton General Hosp., Southampton, England). *Br. Med. J.* 2(6090):826-827; 1977.

7285 BOWEN'S CARCINOMA IN VULVOVAGINAL CROHN'S DISEASE (REGIONAL ENTEROCOLITIS): REPORT OF FIRST CASE. (Eng.) Prezyna, A. P.; Kalyanaraman, U. (Buffalo General Hosp., Buffalo, NY). *Am. J. Obstet. Gynecol.* 128(8):914-916; 1977.

7286 LEVAMISOLE-INDUCED ARTHRITIS IN CROHN'S DISEASE. (Eng.) Segal, A. W.; Pugh, S. F.; Levi, A. J.; Loewi, G. (Clinical Res. Centre, Harrow, Middlesex, England). *Br. Med. J.* 2(6086): 555; 1977.

7287 A CASE OF APPARENT HYPOPITUITARISM COMPLICATING CHRONIC INFLAMMATORY BOWEL DISEASE IN CHILDHOOD AND ADOLESCENCE. (Eng.) Green, J. R. B.; O'Donoghue, D. P.; Edwards, C. R. W.; Dawson, A. M. (St. Bartholomew's Hosp., London EC1A 7BE, England). *Acta Paediatr. Scand.* 66(5):643-647; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

WBC	white blood cells (leukocytes), white blood count
yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7288 GOBLET CELLS IN EMBRYONIC INTESTINE: ACCELERATED DIFFERENTIATION IN CULTURE.

(Eng.) Black, B. L.; Moog, F. (Dept. Biology, Washington Univ., St. Louis, MO 63130). *Science* 197(4301):368-370; 1977.

The course of goblet cell differentiation was studied in duodena of chick embryos. If duodenal tissue from 14-day embryos was cultured in chemically defined medium, more than twice as many goblet cells appeared within 48 hr as in intact embryos during the same time. The increase in goblet cell number was accelerated by 10^{-9} M thyroxine but was prevented by 10^{-6} M hydrocortisone. The results suggest that differentiation of intestinal epithelium is regulated in part by a circulating inhibitor.

7289 PURIFICATION OF HISTAMINE RECEPTOR (IV): SPECIFICITY OF BINDING OF VARIOUS DRUGS TO THE HISTAMINE RECEPTOR-RICH FRACTION AND TO SOLUBILIZED BINDING SITES.

(Eng.) Uchida, M.; Takagi, K. (Dept. Molecular Pharmacology, Meiji Coll. Pharmacy, Setagaya-ku, Tokyo 154, Japan). *Jpn. J. Pharmacol.* 27(1):9-15; 1977.

The binding affinities and specificities of ^{3}H-histamine to the receptor-rich membrane fraction and solubilized sites and its displacement by various agonistic and antagonistic drugs were investigated in the feline small intestine. Scatchard plots of histamine binding to plasma membrane fragments demonstrated two orders of binding sites with binding constants of $K_1=2.1 \times 10^5$ M^{-1} and $K_2=1.3 \times 10^4$ M^{-1} and binding capacities of about 2 and 17 nmol/mg protein, resp. Binding was not only rapid but also reversible. Membrane fragments pretreated with dibenamine exhibited only the lower affinity binding sites in contrast to a preparation protected with diphenhydramine, which exhibited both sites. However, the solubilized receptors exhibited only high affinity, low capacity ($K=1.1 \times 10^5$ M^{-1}, 4 nmol/mg binding sites. Histamine, diphenhydramine, chlorpheniramine, 2-methyl-histamine, and betazole, all H_1-receptor agonists and antagonists, were the most effective competitors of histamine binding. Atropine, 4-methyl-histamine, phetolamine, and propranolol, all H_2 receptor agonists and antagonists, were less effective competitors of histamine binding. Imidazole acetic acid, phytostigmine, phenylephrine, isoproterenol, and carbachol were not effective competitors. The specificities and quantities of binding observed were similar in both the membrane fractions and in the solubilized preparations, indicating that the receptors could be adequately measured both *in vivo* and *in vitro*. However, the calculated number of sites bound to these drugs was higher than expected in some cases, and it is concluded that further work in improving the specificity of binding is required.

7290 MORPHOLOGICAL CHANGES OF THE ADAPTING SMALL INTESTINE DEPRIVED OF GASTRIC, DUODENAL, BILIARY AND PANCREATIC SECRETIONS IN THE RAT.

(Eng.) Fenyo, G. (Dept. Surgery and Surgical Res. Lab., Karolinska sjukhuset, Stockholm, Sweden). *Eur. Surg. Res.* 9(2):122-130; 1977.

The influence of gastrointestinal secretions on adaptive morphological changes in rat small intestine with diminished absorptive surface was investigated. Four groups of Sprague-Dawley rats were operated upon. In group 1 (controls), laparotomy and suture-marking of the small intestine were performed. In group 2, a jejuno-ileostomy was established, resulting in a bypass of about 85% of the small intestine. In group 3, a similar bypass was performed along with diversion of secretions from the duodenum, pancreas, and bile to the transverse colon. In group 4 animals, gastric secretion was diverted to the colon in addition to the operations performed in group 3 animals. No visible macroscopic changes were detectable in group 1 rats. However, in groups 2-4, there was a noticeable hypertrophy of the jejunum and ileum in circuit and also of the first part of the blind loop. The blind loop gradually became narrower towards its top, and its last 20-25 cm was visibly atrophic. In groups 3 and 4, some rats had a grossly dilated colon descendens distal to the jejuno-transversostomy. Increases of wet and dry weight and villus height (% of control values) for group 2 rats amounted to 103, 100, and 29%, resp., for the jejunum, and 141, 123, and 71%, resp., for the ileum. In group 3 animals, the corresponding increases for the jejunum were 11, 96, and 55%, resp.; for the ileum, they were 106, 81, and 40%, resp. Wet weight, dry weight, and villus height increased in group 4 rats by 42, 35, and 9%, resp., for the jejunum, and 23, 16, and 26%, resp., for the ileum. The above experiments demonstrate that the presence of duodeno-pancreatico-biliary secretions is not indispensable for the development of compensatory hypertrophic changes in the small intestine. The importance of gastric secretions in this respect cannot be evaluated because of the serious malabsorption that occurred in group 4 rats as a result of the operations.

7291 RECEPTORS FOR POLYMERIZED ALBUMIN ON LIVER CELLS.

(Eng.) Lenkei, R.; Onica, D.; Ghetie, V. (Dept. Immunology, Victor Babes Inst., Spl. Independentei 99, R-76201 Bucharest 35, Rumania). *Experientia* 33(8):1046-1047; 1977.

The hypothesis that the removal of albumin polymers from the circulation may be performed by specific receptors on liver cells was tested. Using rabbit polymerized albumin either labeled with fluorescein isothiocyanate (FITC-RSAP) or coated on sheep RBC, specific receptors on rabbit liver cells were demonstrated. FITC-RSAP stained more than 90% of the hepatocytes. The majority of fluorescent hepatocytes presented ring and patchy staining. If the cell suspension was incubated for 2 hr at 37 C, many cells exhibited progressive pinocytosis. The intensity of fluorescence was considerably enhanced if the cells had been incubated for 2 hr at 37 C before staining, which may indicate that the *in vivo* cells have loosely attached albumin on their surface that is lost during the incubation at 37 C. No staining was observed with fluorescein isothiocyanate-labeled rabbit albumin. The staining with FITC-RSAP was not reduced by preliminary incubation of cells with nonfluorescent rabbit albumin. No significant staining of rabbit alveolar macrophages or blood lymphocytes was recorded either with FITC-RSA or with FITC-RSAP. These results show that the binding of FITC-RSAP to hepatocytes is specific. The results suggest that there are receptors specific for the fixation and further manipulation of the polymerized albumin on the rabbit hepatocyte membrane.

7292 THE MORPHOGENESIS OF THE LIVER IN THE CHICK EMBRYO--DEVELOPMENT OF THE HEPATIC ENDODERM, THE HEPATIC MESENCHYME, THE ENDOTHELIUM AND MACROPHAGES. (Eng.) Fukuta, S. (Zoological Inst., Univ. Tokyo, Tokyo, Japan). *J. Fac. Sci. Univ. Tokyo Sect. 4* 13(4):341-351; 1976.

7293 THE FUNCTION OF THE HEPATIC ARTERY. (Eng.) Rappaport, A. M.; Schneiderman, J. H. (No affiliation given). *Rev. Physiol. Biochem. Pharmacol.* 76:130-175; 1976.

7294 A SCANNING ELECTRON MICROSCOPY OF SUBCELLULAR STRUCTURES OF THE HUMAN HEPATIC CELL. (Eng.) Itoshima, T.; Shimada, Y.; Hayashi, N.; Murakami, T. (Okayama Univ. Medical Sch., Okayama 700, Japan). *Arch. Histol. Jpn.* 39(1):15-21; 1976.

7295 DEVELOPMENT OF ACINAR CELLS IN THE RAT SUBMANDIBULAR GLAND. (Eng.) Srivastava, H. C. (Medical Coll., Baroda, India). *J. Anat.* 123(2):459-465; 1977.

7296 ULTRASTRUCTURE OF THE PAROTID DUCT. CYTOCHEMICAL STUDIES OF THE STRIATED DUCT AND PAPILLARY CYSTADENOMA LYMPHOMATOSUM OF THE HUMAN PAROTID GLAND. (Eng.) Cutler, L. S.; Chaudhry, A.; Innes, D. J., Jr. (Univ. Connecticut Health Center, Farmington, CT 06032). *Arch. Pathol. Lab. Med.* 101 (8):420-424; 1977.

ABSORPTION - EXCRETION - TRANSPORT

7297 MOTILITY- AND BLOOD FLOW-DEPENDENT ABSORPTION OF AMINO ACIDS IN CANINE SMALL INTESTINE. (Eng.) Pytkowski, B.; Michalowski, J. (Medical Center Postgraduate Education, Marymoncka 99, 01-813 Warsaw, Poland). *Eur. J. Clin. Invest.* 7(2): 79-86; 1977.

The relation between L-phenylalanine and L-serine absorption, intestinal motility, and blood flow was studied with a canine *in situ* isolated jejunal loop in acute experiments and in chronic preparations in conscious dogs. During spontaneous rhythmic contractions, as well as after mechanical and pharmacological (i.e., pilocarpine or acetylcholine) stimuli, rhythmic changes in blood flow, related to intestinal contractions, were observed. They had no bearing on mean blood flow or absorption as long as they did not occur together with tonic contractions. The tonic contractions resulted in a prolonged decrease in jejunal blood flow and diminished amino acid absorption rate. Absorption and motility index, as well as blood flow and motility were negatively correlated. There was a positive rectilinear correlation between intestinal blood flow and absorption, regardless of whether changes in blood flow resulted from the increase in motility or were induced by intestinal artery occlusion. These correlations suggest that changes in amino acid absorption during increased motility depend on changes in blood flow. This relationship may be important in clinical syndromes with hypermotility.

7298 MECHANISM OF INTESTINAL ABSORPTION AND BRAIN UPTAKE OF L-5-HYDROXYTRYPTOPHAN IN RATS, AS COMPARED TO THOSE OF L-3,4-DIHYDROXYPHENYLALANINE. (Eng.) Shindo, H.; Komai, T.; Kawai, K. (Central Res. Lab., Sankyo Co., Ltd., Hiromachi 1-chome, Shinagawa-ku, Tokyo, Japan). *Chem. Pharm. Bull.* 25(6):1417-1425; 1977.

L-5-hydroxytryptophan (5-HTP) and L-3,4-dihydroxyphenylalanine (dopa) were compared with respect to their mechanisms of intestinal absorption, metabolism in the intestine and liver, and mechanisms of passage through the blood-brain barriers *in vitro* or *in situ* in the rat. The corresponding D-isomers were also investigated for comparison. L-5-HTP, but not the D-isomer, was absorbed from the intestine by an active transport mechanism in the same way as L-dopa. *In vitro* studies using rat brain cortex slices showed that both L-5-HTP and L-dopa, but not their D-isomers, are taken up by the brain tissues by an active transport mechanism that is saturable, energy-dependent, and competitive. There was no substantial difference between L-5-HTP and L-dopa in the rate of intestinal absorption and that of brain uptake. L-5-HTP was decarboxylated in the intestine to a much lesser extent than L-dopa during absorption, and the decarboxylation activity of rat intestine and liver homogenates was found to be about four and seven times higher for L-dopa than for L-5-HTP, resp. The latter results suggest that a p.o. dose of L-5-HTP can be much more easily transferred into the circulating blood, without undergoing significant decarboxylation in the peripheral organs, than can L-dopa, resulting in a more efficient penetration of L-5-HTP into the brain as a serotonin precursor.

7299 INTESTINAL ABSORPTION AND RETENTION OF CADMIUM IN NEONATAL RAT. (Eng.) Sasser, L. B.; Jarboe, G. E. (Comparative Animal Res. Lab., Oak Ridge, TN 37830). *Toxicol. Appl. Pharmacol.* 41(2):423-431; 1977.

To quantitate systemic cadmium absorption and to determine the pattern of intestinal uptake and retention of cadmium, newborn Sprague-Dawley rats were dosed p.o. at 2 or 24 hr of age with 1 µCi of ^{115m}Cd and killed at intervals between 1 and 21 days after dosing. Systemic cadmium absorption was about six times greater in 2-hr-old pups as compared with 1-day-old pups, but the rate of absorption after day 1 was similar in both age groups. Post-weaning rats dosed at 6 weeks of age absorbed 0.5% of the Cd dose, resp. Cadmium was tenaciously retained in the gastrointestinal tract of newborn rats, with over 60% of the Cd dose remaining in the gastrointestinal tract 15 days after dosing. Autoradiographs showed considerable amounts of radioactivity not only in the intestinal surface epithelium and brush borders, but also in the crypts, lamina propria, and muscular layer. Because of the greater absorption and the prolonged intestinal retention of Cd in the newborn rat and the long biological half-life of Cd in the body, Cd exposure in infancy could result in greater lifetime Cd accumulation. The prolonged intestinal retention of Cd may have significant implications for the interpretation of short-term balance studies of metals.

7300 STEADY-STATE METABOLISM AND TRANSPORT OF D-GLUCOSE BY RAT SMALL INTESTINE IN VITRO. (Eng.) Pritchard, P. J.; Porteous, J. W. (Dept. Biochemistry, Univ. Aberdeen, Marischal Coll., Aberdeen AB9 1AS, Scotland). *Biochem. J.* 164(1):1-14; 1977.

The translocational and metabolic fate of D-glucose was studied in the *in vitro* rat small intestine under defined conditions. Conditions of incubation of the everted sacs were selected to ensure that absorption of D-glucose by the mucosal tissue, intracellular metabolism of the absorbed glucose, and transport of glucose through the intact intestinal tissue proceeded linearly with respect to time of incubation within stated intervals. Under these conditions, steady intracellular concentrations of glucose and lactate were demonstrated. About 25% of the glucose absorbed from the external mucosal solution was temporarily accumulated within the mucosal tissue and about 25% was transported through the intact tissue into the external serosal solution; the remainder of the absorbed glucose was metabolized, 90% to lactate and 10% to CO_2. Concomitant respiration rates were comparable with those reported for several other preparations of intestine and were stoichiometrically in excess of the O_2 metabolism required to account for the production of CO_2 from the absorbed glucose. Water transport through the everted sacs proceeded at an optimum rate under the experimental conditions selected. Other factors that influenced the design of the experiments and the interpretation of results included the initial physiological state of the animal, the anesthetic used, and the ionic composition of the incubation medium.

7301 EFFECT OF SODIUM TAUROCHOLATE AND ETHANOL ON HYDROGEN ION ABSORPTION IN RABBIT ESOPHAGUS. (Eng.) Chung, R. S. K.; Johnson, G. M.; Denbesten, L. (Veterans Admin. Hosp., Iowa City, IA 52240). *Am. J. Dig. Dis.* 22(7):582-588; 1977.

H^+ absorption by the rabbit esophagus was studied during *in vivo* perfusion of the esophagus with a solution of 0-140 mM H^+ containing 5 mM sodium taurocholate (NaTC) or 5% ethanol (E). Net ion and volume fluxes, changes in osmolality and potential difference (PD), histological alterations, and absorption of NaTC or E were correlated with concentration of H^+ in the perfusate. Both agents markedly increased the rate of removal of H^+ from the esophageal lumen; this removal was accompanied by a fall in PD and a net increase in the transport of Na^+, K^+, and Cl^- ions in the direction of their chemical gradients as well as by a decrease in osmolality in the recovered perfusate. Neutral solutions of E depressed PD and increased net ion fluxes to a lesser extent than did acid solutions, and acidity did not affect absorption of E. NaTC in neutral solution did not induce changes in PD or in net ion fluxes, nor was it absorbed; absorption of NaTC increased with acidity. Damage to the esophageal mucosa (extensive thrombosis, necrosis, spontaneous rupture) was more severe after perfusion with an acid solution of NaTC than with E. For both agents, histological changes were proportional to H^+ concentration. The data suggest that increased permeability of the esophageal mucosa is the basic mechanism underlying esophagitis.

7302 IMPORTANCE OF LUMINAL LECITHIN IN INTESTINAL ABSORPTION AND TRANSPORT OF LIPID IN THE RAT. (Eng.) Tso, P.; Simmonds, W. J. (Dept. Physiology, Univ. Western Australia, Nedlands, 6009

Western Australia). *Aust. J. Exp. Biol. Med. Sci.* 55(3):355-357; 1977.

The importance of luminal lecithin in the intestinal absorption and transport of lipid was studied in rats, and the stomach emptying and uptake from the lumen were measured. Control and bile fistula male Wistar rats received 5 ml of a test meal made up of lipid (labeled with ^{14}C-oleic acid) and bile salts via a gastric tube; the test meal in some cases also contained about 65 µmol of egg lecithin (50 mg). There was no significant differences in stomach emptying or absorption in the two subgroups of bile fistula rats. At 2 hr after the test meal administration, the percentage of administered radioactive dose recovered from the mucosa was the same for control and the two bile fistula groups. However, at 4 hr, there was a significant ($p<0.01$) increase in mucosal recovery in controls as compared to the other two groups. The control rats transported significantly more lipid than the bile fistula groups at 4 hr ($p<0.05$) but not at 2 hr. If the amount of radioactive lipid transported was expressed as percent dose absorbed, the percentage stayed constant (83%) in all three groups at 2 and 4 hr. This finding implies that transport is related to absorption. The results do not support the previous suggestion that chylomicron formation and release are impaired in bile fistula rats. No evidence was found that luminal lecithin plays an important role in the transport of absorbed fat as chylomicrons.

7303 EFFECTS OF PROTEIN SYNTHESIS INHIBITORS ON ANGIOTENSIN-STIMULATED AND ANGIOTENSIN-INHIBITED FLUID TRANSPORT BY RAT JEJUNUM IN VIVO. (Eng.) Bolton, J. E.; Munday, K. A.; Parsons, B. J. (Dept. Physiology and Biochemistry, Univ. Southampton, Southampton SO9 3TU, England). *J. Endocrinol.* 74(2): 213-221; 1977.

The effects of protein synthesis inhibitors on the *in vivo* jejunal responses to i.v. infusions of angiotensin were studied in Wistar rats. Actinomycin D (600 µg/kg, i.v.) had no effect on the stimulation of fluid transport, which followed the infusion of low doses of angiotensin (0.59 ng/kg/min). Cycloheximide (0.1 or 2 mg/kg), blocked the stimulatory response to angiotensin, but was without effect on the inhibitory response to high doses of the hormone (590 ng/kg/min). It is concluded that low (physiological) doses of angiotensin stimulate fluid transport by a mechanism involving protein synthesis at a stage later than transcription, whereas high doses of the hormone inhibit fluid transport by a process that does not require protein synthesis.

7304 THE SELECTIVE UPTAKE AND TRANSMISSION OF PROTEINS TO THE CIRCULATION FROM THE SMALL INTESTINE OF THE SUCKLING RAT. (Eng.) Jones, R. E. (Dept. Zoology, Univ. Coll. North Wales, Bangor, Gwynedd, North Wales, United Kingdom). *Biochim. Biophys. Acta* 451(1):151-160; 1977.

The uptake of various ^{131}I- or ^{125}I-labeled protein mixtures from the small intestine of 14-day-old Wistar rats was measured after oral or intraluminal administration of the proteins. Mixtures were administered orally by a polythene stomach tube. Intraluminal injection of mixtures was performed after laparotomy and ligation of intestine at the ileocecal junction and at the pyloric sphincter. The mixtures containing various combinations of labeled bovine, rat, and sheep IgG and bovine albumin were given in doses of 0.2 ml NaCl, with a total dose of 300 µg of protein. Concentrations in sera 4 hr after oral administration were lower than after intestinal injection, possibly as a result of gastric hydrolysis. The concentration in the sera 4 hr after intraluminal administration was higher when proteins were injected into the isolated proximal small intestine than when they were injected into the distal small intestine. Sera concentrations also indicated greater selectivity in protein uptake by the proximal intestine. When the distribution of proteins was measured in small intestinal walls 1 hr after administration, the proximal intestine demonstrated selective uptake of the homologous IgG, while paired homologous and heterologous IgG was observed in equal concentrations in the wall of the distal small intestine. Measurement of proteins in the gut washings and sera indicate that the specific uptake of proteins by the cells of the proximal intestine is insufficient to account wholly for the process of selective transport to the circulation. Specific uptake may be a first step in this process.

7305 WATER ABSORPTION AND SWELLING IN THE RAT SMALL INTESTINE IN VITRO. (Eng.) Esposito, G.; Csaky, T. Z. (Istituto di Fisiologia Generale e di Chimica Biologica, Universita degli Studi di Milano, via Mangiagelli 32, I-20133, Milano, Italy). *Pfluegers Arch.* 369(1):75-78; 1977.

Net mucosal-to-serosal water transport and water retention as functions of time were simultaneously measured in the isolated, everted rat jejunum and ileum. The swelling of the epithelium preceded the absorption of fluid, and then it remained constant throughout the experiment. The water uptake, determined as a weight increase, and the net water transport, determined as a serosal volume increase, were higher in Krebs-Ringer-bicarbonate medium than in a Krebs-Ringer-phosphate medium. In the jejunum, glucose markedly stimulated both the tissue retention and the net transport of water, but these effects were not seen in the ileum. The replacement of chloride with sulfate in the medium diminished both water transport and retention, but both were markedly stimulated by the addition of glucose. The results show that during water transport the epithelial layer swells, and the swelling increases when the amount of water transported is increased.

7306 STUDIES ON THE INTESTINAL ABSORPTION OF BOVINE XANTHINE OXIDASE. (Eng.) Volp, R. F.; Lage, G. L. (Sch. Pharmacy, Univ. Wisconsin, Madison, WI 53706). *Proc. Soc. Exp. Biol. Med.* 154 (4):488-492; 1977.

The fate of xanthine oxidase at the pH of the stomach was investigated using a low pH buffer, and the absorption of this enzyme was studied in the everted rat intestine. Xanthine oxidase activity was determined by liquid scintillation counting of ^{14}C-uric acid formed by the action of the enzyme on ^{14}C-xanthine. Treatment of milk with a low pH buffer resulted in irreversible loss of xanthine oxidase activity. There was no significant difference between enzyme activities in serosal fluid or intestinal homogenates from everted gut strips incubated in Krebs buffer alone and those incubated in Krebs buffer plus milk, nor was there a difference between either of these and the control. The results show that the proposal that xanthine oxidase passes through the stomach and is absorbed intact by the small intestine is implausible.

7307 DETERMINATION OF EXTRACELLULAR SPACE IN SMALL INTESTINE.

(Eng.) Hajjar, J. J.; Bitar, K. (Sch. Medicine, American Univ. Beirut, Beirut, Lebanon). *Comp. Biochem. Physiol.* [*A*] 56A(4):615-619; 1977.

The extracellular space (ECS) of the turtle small intestine was characterized in the mucosal and submucosal layers (using ^{14}C-D sorbitol, ^{14}C-inulin, ^{22}Na, ^{14}C-D-mannitol, and 131-radioiodinated serum albumin [RISA] as probing solutes) by exposing only one surface at a time of the intestinal strip to each solute. The effects of changes in cell volume on the ECS were studied by changing the osmolarity or temperature of the incubation solution. The ECS values differed widely with the different probing solutes. Inulin uptake achieved an equilibrium value (1.6 µl/mg dry weight) in the first 30 min and maintained this value for 2.5 hr. Regardless of the method of exposure to the probing solute, the mucosal space (0.08 ± 0.002 ml/g wet weight) remained smaller than the submucosal space (0.16 ± 0.02 ml/g wet weight), suggesting that inulin could not penetrate between the two layers. RISA, of similar molecular weight, produced similar results. Sorbitol, which has a smaller molecular weight than inulin or RISA, did not differentiate between the two layers and occupied a much larger ECS (2.8 µl/mg dry weight at 30 min) than did inulin. Furthermore, sorbitol uptake never reached equilibrium, although the greatest increase occurred within the first 60 min. Mannitol and ^{22}Na, also of small molecular weight compared to inulin or RISA, produced results similar to those with sorbitol. Using inulin as a probe, the ECS varied inversely with changes in cell volume. The mucosal inulin space was shown to account for most of the change. It is concluded that, for experiments involving more than 30-40 min incubation times, inulin is the most useful probe due to its ability to differentiate between the mucosal and submucosal layers and to the fact that it rapidly achieves equilibrium. However, since inulin occupied approximately 60% of the sorbitol and mannitol space in the submucosa and muscularis and about 32% of the mannitol space in the mucosa, a correction factor must be employed.

7308 ELECTRICAL CHANGES IN ISOLATED RAT JEJUNUM INDUCED BY HYPERTONICITY.

(Eng.) Garcia-Diaz, J. F.; Corcia, A. (Seccion de Biofisica, Facultad de Medicina, Universidad de Malaga, Spain). *Biochem. Biophys. Acta* 468(2):177-187; 1977.

The electrical response of isolated jejunum from Wistar rats to changes in the osmolarity of the mucosal and serosal bathing media was investigated. When the bathing solution contained 20 mM of D-glucose, the transepithelial potential difference (PD, serosal solution positive) at 30 min averaged 8.6 ± 0.3 mV. Mannitol-induced mucosal hypertonicity produced a drop in the PD with a half-time of about 15 sec; the change in PD was -7.4 ± 0.4 mW when 170 mM mannitol was added and -4.4 ± 0.4 mV following the addition of 85 mM mannitol. When both the mucosal and serosal solutions were made hypertonic simultaneously by mannitol addition, the PD changed in the same way as when only the mucosal solution was made hypertonic. When 170 mM mannitol was added to the serosal solution only, the PD fell slowly during the first 15 sec and then rose to a stable value at 35 min, with the difference in PD values before and after mannitol addition being 0.5 ± 0.1 mV; this difference was significantly different from zero ($p<0.01$). There was no significant difference between the relative changes in PD and short-circuit current, suggesting that there was no change in the transmural electric resistance values due to osmotic effects. When the PD was varied by adding different concentrations of glucose to the bathing media (using mannitol to maintain the isotonicity of the initial bathing solution), the PD value at 30 min after the addition of 20 mM glucose averaged 8.6 ± 0.5 mV; with 5 mM glucose plus 15 mM mannitol, the PD averaged 4.0 ± 0.3 mV; and when glucose was completely replaced by mannitol (20 mM), the PD was 1.0 ± 0.1 mV. The potential drop induced by mucosal hypertonicity was linearly related to the magnitude of the PD just before the increase in osmolarity. The drop in potential can be explained by a decrease in the electrical resistance of the extracellular shunt pathway due to an opening of the tight junctions. The results can be accounted for in terms of an equivalent electrical circuit for the small intestine, which makes it possible to obtain estimates of the values of the diffusion potential and the salt gradient across the tight junction.

MOTILITY

7320 AUTOMATED HIGH-SPEED ANALYSIS OF GASTROINTESTINAL MYOELECTRIC ACTIVITY. (Eng.) Wingate, D.; Barnett, T.; Green, R.; Armstrong-James, M. (London Hosp. Medical Coll., Turner St., London E.1, England). *Am. J. Dig. Dis.* 22(3): 243-251; 1977.

An automated system for the high-speed analysis of gastrointestinal myoelectric activity using high-speed tape replay is described. Replay speed (120 mm/sec) is 60 times the recording speed, so that 1 sec of replay time is equal to 1 min of recording (real) time. Data analysis is performed using digital counting and an averaging computer. Rapid replay not only reduces the time required for data retrieval, but also increases the frequency of the recorded signals to allow for electronic separation of fast and slow wave activity for on-line conversion into digital pulses suitable for computer analysis. The technique is illustrated by the analysis of a single prolonged multichannel recording of myoelectric activity in two mongrel dogs fitted with eight monopolar electrodes on the serosa of the gastrointestinal tract. Recording was undertaken continuously from the conscious fasted animal for 570 min. Similar numbers of spikes were counted in duodenal and jejunal recordings (2,772 and 2,444, resp.), but activity was apparently greater in the ileum and antrum (9,653 and 21,324 spikes, resp.). The pure exponential nature of the antral recording suggested that the spikes were artifacts, and at autopsy, it was found that the conducting lead to the gastric antrum had fractured. On the basis of the interval histogram, the antral recording was discarded, and the ileum recording was regarded with some suspicion. Pulse density histograms of the complete duodenal and jejunal recordings were constructed with the averaging computer and clearly showed bursts of interdigestive myoelectric activity separated by intervals of quiescence. An examination of the distribution of spikes from two leads in 12 consecutive 10-min recording periods for duodenal and jejunal activity reveals not only peaks of activity, but also their aboral migratory nature, as they occur later in the jejunum than in the duodenum. Digital counting quantifies myoelectric events, and this may prove to be important in assessing the myoelectric response to exogenous stimuli.

7321 SITE OF ACTION OF CATECHOLAMINES ON THE PERISTALTIC REFLEX. (Eng.) Perucca, E.; Teggia, M.; Tonini, M. (Inst. Medical Pharmacology, Univ. Pavia, Pavia, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(9):581-586; 1976.

To clarify the site of peristaltic reflex regulation, the efficiency of sympathetic stimulation in inhibiting peristalsis and the contractile response to several drugs were investigated in the cat and guinea pig distal colon. Peristalsis was induced by insertion of an intraluminal balloon, and the periarterial plexus of the inferior mesenteric artery was stimulated at low frequencies. The drugs tested were acetylcholine chloride (0.2 µg injected intraarterially) and piperoxan HCl and propranolol HCl (each, 1×10^{-7} g/ml added to the organ bath). In the cat, stimulation of the periarterial nerves blocked peristalsis by abolishing the mechanical response of the longitudinal and circular muscle layers. A few seconds after the end of stimulation, however, peristalsis resumed. Sympathetic stimulation did not influence the contractile response of the longitudinal and circular muscles to acetylcholine, which produced a contraction of similar amplitude to the one produced by the balloon. The peristaltic reflex and its inhibition by sympathetic stimulation were the same in the guinea pig. Piperoxan, but not propranolol, abolished the block of peristalsis due to sympathetic stimulation. It is suggested that the adrenergic system inhibits peristalsis through a depression of cholinergic neuron activity. Although the catecholamines have a direct effect on the muscle cells, the main mechanism regulating the peristaltic reflex is inhibition of the intrinsic nervous structures.

7322 GASTRIC MOTILITY AND EMPTYING FOLLOWING PARIETAL CELL VAGOTOMY AND SELECTIVE GASTRIC VAGOTOMY. EXPERIMENTAL INVESTIGATION. (Eng.) Mikkelsen, K.; Eriksen, P. O.; Bone, J. (Kommunehospitalet, Univ. Aarhus, Aarhus, DK-8000, Denmark). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 17(5B): 714-722; 1976.

In adult mongrel dogs, the effect of the following three surgical procedures on gastric motility and the hormonal phase of gastric secretion was studied: (1) parietal cell vagotomy without drainage, (2) parietal cell vagotomy plus gastroduodenal anastomosis, (3) selective gastric vagotomy (cutting the antral nerves) plus parietal cell vagotomy, and (4) gastric and parietal cell vagotomies plus gastroduodenal anastomosis. In all dogs, a Heidenhain pouch (HP, a denervated fornix pouch) was constructed prior to the other procedure. Gastric motility and emptying of a meal of 200 g of standard dog food in dogs with HP alone was the baseline for comparison of the experimental results. Antral motility and gastric emptying time were unaffected by parietal cell vagotomy. Addition of anastomosis to the parietal cell vagotomy decreased motility but did not have a significant effect on mean emptying time. When the antral nerves were cut, complete atony of the stomach occurred. Emptying rate was unaltered in animals who had vagotomies plus gastroduodenal anastomosis because the standard meal passed passively through the anastomosis. Selective gastric vagotomy plus parietal cell vagotomy without anastomosis caused atony and significantly ($p<0.005$) prolonged emptying time. It is suggested that the "dumping" effect observed in duodenal ulcer patients who have undergone a combined parietal cell vagotomy and anastomosis may be the result of a decrease in the rate of emptying of the stomach. Parietal cell vagotomy without anastomosis is recommended as the procedure of choice for treatment of duodenal ulcer.

SECRETION AND METABOLISM

7336 α-ADRENERGIC RECEPTORS IN RAT PAROTID CELLS. I. CORRELATION OF [^{3}H]DIHYDROERGOCRYPTINE BINDING AND CATECHOLAMINE-STIMULATED POTASSIUM EFFLUX. (Eng.) Strittmatter, W. J.; Davis, J. N.; Lefkowitz, R. J. (Durham Veterans Admin. Hosp., Durham, NC 27705). *J. Biol. Chem.* 252(15):5472-5477; 1977.

The binding of [^{3}H]dihydroergocryptine was used to characterize the α-adrenergic receptor binding sites in both parotid membranes and dissociated parotid acinar cells of Sprague-Dawley rats. [^{3}H]dihydroergocryptine bound rapidly to both the membranes and dissociated cells. The association rate constant in membranes was 1.7×10^7 l/mol/min at 20 C. In cells [^{3}H]dihydroergocryptine binding reached equilibrium within 10 min. [^{3}H]dihydroergocryptine binding was saturable in membranes with 29.7 fmol bound/mg of protein and a dissociation constant of 10.5 nM. [^{3}H]dihydroergocryptine binding to cells rendered hypoxic or frozen and thawed was saturable with approximately 15,000 sites/cell. By contrast, binding to incubated, oxygenated cells did not saturate at concentrations of [^{3}H]dihydroergocryptine up to 20 nM. [^{3}H]dihydroergocryptine binding closely correlated with measurements of K^+ release. The ability of eight adrenergic agents to displace [^{3}H]dihydroergocryptine correlated (r=0.98) with their ability to stimulate or block K^+ release and had the typical potency series expected for an α-adrenergic receptor (epinephrine>norepinephrine>>isoproterenol; [-]-epinephrine>[+]-epinephrine; [-]-norepinephrine>[+]-norepinephrine). K^+ efflux generated by α-adrenergic stimulation reached a maximum at 30-60 sec. K^+ was then taken up by the cells with a half-time of 4 min. This uptake was blocked by ouabain. The maximum release of K^+ by 10^{-3} M epinephrine in the presence of 10^{-3} M ouabain was 2.3 μg of $K^+/10^6$ cells. Since each cell possesses 15,000 binding sites, 2.3×10^6 molecules of K^+ are released per binding site. If 60 sec are required for release, 4×10^4 molecules of K^+/binding site/sec are released.

7337 α-ADRENERGIC RECEPTORS IN RAT PAROTID CELLS. II. DESENSITIZATION OF RECEPTOR BINDING SITES AND POTASSIUM RELEASE. (Eng.) Strittmatter, W. J.; Davis, J. N.; Lefkowitz, R. J. (Durham Veterans Admin. Hosp., Durham, NC 27705). *J. Biol. Chem.* 252(15):5478-5482; 1977.

The attenuation by epinephrine of K$^+$ release from dissociated rat parotid acinar cells and the factors that influence its development (desensitization) and reversal (resensitization) were characterized. Preincubation of dissociated rat parotid acinar cells with 10^{-3} M epinephrine produced a time- and concentration-dependent decrement in the α-adrenergic response of the cells, K$^+$ release. This receptor desensitization by epinephrine was specific for the α-adrenergic receptor of the acinar cells, since K$^+$ release by the muscarinic cholinergic agonist, carbachol, remained unchanged. The half-time for desensitization was 2 min at 38 C. Chelation of Ca^{2+} with 10^{-3} ethylene glycol bis(β-aminoethyl ether)*N,N'*-tetraacetic acid prevented epinephrine-induced K$^+$ release, but did not prevent desensitization. The α-adrenergic antagonist, phentolamine (10^{-4} M), did not produce desensitization, but blocked the desensitization caused by epinephrine. Desensitized cells slowly resensitized when incubated in the absence of agonist. Depolarization of the acinar cell membrane potential by elevating external K$^+$ concentration or incubating in ouabain markedly accelerated resensitization. Desensitization and resensitization of the α-adrenergic biological response were accompanied by parallel changes in the α-adrenergic receptor binding sites assessed by [^{3}H]dihydroergocryptine binding. These data are the first demonstration of α-adrenergic receptor desensitization. In rat parotid acinar cells, rapid alterations in membrane binding sites contribute to desensitization and resensitization of the α-adrenergic response and, as in the cholinergic receptor of muscle, the membrane voltage appears to regulate the rate of receptor resensitization.

7338 ETHANOL-INDUCED INHIBITION OF GUANYLATE CYCLASE IN LIVER, PANCREAS, STOMACH, AND INTESTINE. (Eng.) Vesely, D. L.; Levey, G. S. (Univ. Miami Sch. Medicine, Miami, FL 33152). *Res. Commun. Chem. Pathol. Pharmacol.* 17(2):215-224; 1977.

Ethanol-induced inhibition of soluble preparations of guanylate cyclase from the liver, pancreas, stomach, and ileum of male Sprague-Dawley rats is reported. At a concentration of 5%, ethanol inhibited liver, pancreas, ileum, and stomach guanylate cyclase by 100, 85, 96, and 98%, resp. ($p<0.001$). Before ethanol addition, the levels of cyclic guanosine 3',5'-monophosphate (cyclic GMP, pmol accumulated/mg protein/10 min incubation) in liver, pancreas, ileum, and stomach tissues were 279 ± 6, 224 ± 6, 592 ± 6, and 453 ± 6, resp., whereas, after ethanol addition, the corresponding values were 0, 34 ± 4, 25 ± 3, and 8 ± 2, resp. Studies on the effects of different doses of ethanol on hepatic guanylate cyclase revealed that ethanol concentrations of 2.5 and 5.0% resulted in maximal inhibition (100%) of hepatic guanylate cyclase, whereas ethanol concentrations of 1.0% or less had no significant inhibiting effect on guanylate cyclase. The inhibitory effects of ethanol on the guanylate cyclase-cyclic GMP system of the above tissues provide a possible explanation for some of the diverse effects of ethanol on these tissues.

7339 IN VIVO STUDIES OF PRODUCTION AND UTILIZATION OF LACTIC ACID IN THE RAT. ROLE OF THE DIGESTIVE TRACT. (Fre.) Remesy, C.; Demigne, C.; Aufrere, J. (Station de Physiopathologie de la Nutrition, I.N.R.A., Theix, Saint Genes Champanelle, 63110 Beaumont, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):607-613; 1977.

Lactic acid levels were measured and related to pH in the stomach (secretory and nonsecretory zones), duodenum, jejunum, ileum, and cecum of male Sherman rats fed cereal-based or synthetic diets for 10 days. Diet 1 had a wheat and corn base supplemented with soya cakes and molasses. Diet 2 was semisynthetic and consisted of 13% casein, 79% wheat starch, corn oil, vitamins, and minerals. Diet 3 was similar to diet 2 except that potato starch replaced the wheat starch in proportions varying from 20-79%. Rats fed diet 1 had a pH of 5 and high levels of D-lactic acid in the nonsecretory zone of the stomach, which indicated that the lactic acid was produced by microbial fermentation. In the small intestine, L-lactic acid, which is produced by endogenous glycolysis, increased and D-lactic acid decreased. In the cecum, D- and L-lactic acid levels increased above 8 mM only when the pH fell below 5; volatile fatty acids predominated. Rats fed diets 2 and 3 had very low levels of lactic acid, principally L-lactic acid, in the stomach and small intestine. In the cecum, only rats fed diet 3 had considerable amounts of both D- and L-lactic acid and a pH below 5. Arteriovenous differences in lactate concentration in the liver, stomach, small intestine, and cecum showed that the jejunum was the site of highest glucose uptake and lactate production. However, lactate production by the jejunum was markedly lower in fasting rats than in rats fed diet 2. Glucose consumption accounted for most of the lactate excreted by the rats.

7340 CALCIUM ION UPTAKE INDUCED BY CHOLINERGIC AND α-ADRENERGIC STIMULATION IN ISOLATED CELLS OF RAT SALIVARY GLANDS. (Eng.) Koelz, H. R.; Kondo, S.; Blum, A. L.; Schulz, I. (Stadtspital Triemli, Birmensdorfer-Strasse 497, CH-8063 Zurich, Switzerland). *Pfluegers Arch.* 370(1): 37-44; 1977.

7342 CENTRAL NORADRENERGIC INHIBITION OF GASTRIC MUCOSAL BLOOD FLOW AND ACID SECRETION IN RATS. (Eng.) Osumi, Y.; Aibara, S.; Sakae, K.; Fujiwara, M. (Dept. Pharmacology, Kyoto Univ., Sakyo-ku, Kyoto 606, Japan). *Life Sci.* 20(8):1407-1416; 1977.

To investigate the role of central noradrenalin (NA) in gastric functions, changes in mucosal blood flow (MBF) and acid secretion following electrical stimulation of the lateral hypothalamic area (LHA) and the effects of NA on these parameters were examined in anesthetized Wistar rats. NA (10 μg) injected into the lateral ventricle decreased the basal value of both the gastric MBF and acid output, while the same dose of acetylcholine or dopamine was without effect. Repetitive electrical stimulation of LHA at 10 cycles/sec, 0.5 mA, 2 msec for 10 min elicited a significant, reproducible increase in both gastric MBF and acid output. NA (10 μg) injected into the lateral ventricle completely blocked these increases induced by the electrical stimulation. These data suggest that a central noradrenergic inhibitory mechanism is involved in the regulation of the gastric MBF and acid secretion.

7343 REDOX INVOLVEMENT IN ACID SECRETION IN THE AMPHIBIAN GASTRIC MUCOSA. (Eng.) Rabon, E. C.; Sarau, H. M.; Rehm, W. S.; Sachs, G. (Lab. Membrane Biology, Univ. Alabama Birmingham, Birmingham, AL 34294). *J. Membr. Biol.* 35(3):189-204; 1977.

Gastric fundic metabolism was studied spectroscopically in frog mucosa during transitions of secretory status *in vitro* and by direct measurement of pyridine nucleotides and associated metabolites in biopsies of dog fundic mucosa also during secretory transition. In the frog, inhibition of spontaneous secretion by burimamide resulted in oxidation of the redox components from flavin adenine dinucleotide (FAD) to cytochrome a_3. Addition of histamine resulted in reduction of these components with onset of secretion by about 50%. In contrast, the effect of burimamide, and subsequently histamine, on the NAD^+:NADH ratio was relatively slight. The presence of burimamide substantially reduced the effect of amytal on the pyridine nucleotide spectrum and abolished the effect of amytal on FAD and the cytochromes. Measurement of lactate, pyruvate, α-ketoglutarate, NH_3, and glutamate in the dog showed that, whereas the calculated NAD^+:NADH ratio in the cytoplasm declined with onset of secretion, the calculated mitochondrial ratio rose. No change was noted in the $NADP^+$:NADPH ratio. It is concluded that (1) H_2 antagonists act by blocking substrate flow into the mitochondrial respiratory chain, (2) conversely, histamine stimulation acts at the level of substrate mobilization, and (3) there may be a cross-over in the mitochondrial chain between NAD^+ and FAD.

7344 EFFECT OF DUODENAL ACIDIFICATION ON GASTRIC MUCUS AND ACID SECRETION IN CONSCIOUS CATS. (Eng.) Vagne, M.; Perret, G. (INSERM U 45, Pavillon Hbis, Hopital E.-Herriot, F-69374 Lyon Cedex 2, France *Digestion* 14(4):332-341; 1976.

Cats, previously prepared with a Heidenhain pouch (HP) and a gastric fistula (GF), were used to determine the effect on mucus, acid, and pepsin secretion of endogenously released duodenal hormones. The hormones were released by closing the GF, during gastric acid secretion induced by the i.v. infusion of pentagastrin (32 μg/kg/hr) or histamine (0.32 μg/kg/hr), for 15-min periods. Acid entering the duodenum caused release mostly of secretin, but also of cholecystokinin (CCK), and previous studies with exogenously administered secretin and CCK have resulted in stimulation of pepsin and mucus in cats. The release of endogenous duodenal hormones produced by closing the GF also induced a stimulation of pepsin and mucus secretions in the HP, and, in addition, there was an increase in acid. Since the gastrointestinal hormones secretin and CCK were not considered to be responsible for this effect, it is suggested that another factor released by the duodenum stimulates the production of gastric acid secretions.

7345 THE EFFECT OF ACID-STIMULATING AND INHIBITING DRUGS ON THE ULTRASTRUCTURE OF GASTRIC PARIETAL CELLS IN MAN. (Eng.) Pillay, C. V.; Somers, S.; Booyens, J.; Moshal, M. G.; Bryer, J. V. (Dept. Physiology, Univ. Durban-Westville, Durban, South Africa). *S. Afr. Med. J.* 51(25):915-919; 1977.

The ultrastructure of human parietal cells at rest was studied after stimulation of gastric acid secretion by pentagastrin and after inhibition with the anticholinergic drug propantheline or with the histamine H_2-receptor antagonist cimetidine. Biopsy specimens of the fundus of the stomach from patients referred for upper gastrointestinal endoscopy were taken 1 hr after the i.m. administration of 6 μg pentagastrin and 1 hr after the i.v. administration of either 100 mg cimetidine or 30 mg propantheline. The ultrastructure of parietal cells 1 hr after pentagastrin stimulation showed a decrease in the number of vesicles and tubules and an increase in the number of microvilli in the canaliculus and gastric gland. The opposite occurred 1 hr after inhibition of gastric acid secretion by either cimetidine or propantheline, with an increase in the number of vesicles and tubules and a decrease in the number of microvilli in the canaliculi being observed. These observations support the hypothesis that, during secretion of acid, the tubulovesicular system increases the secretory surface of the lumen of the gastric gland and the canaliculus by a process of eversion or fusion of the vesicles and tubules with the plasmalemma. On inhibition of acid secretion, there is thought to be a reformation of the tubulovesicular system by pinocytosis. An observed increase in lysosomal activity after the administration of the two inhibiting drugs may possibly be involved in reducing the quantity of membrane following the membrane flow that occurs on gastric acid inhibition.

7346 ANTACIDS AND GASTRIC MUCOSA: PROTECTIVE EFFECT OF AN ANTACID ON ACETYLSALICYLIC ACID-INDUCED FUNCTIONAL CHANGES IN HUMAN GASTRIC MUCOSA. (Ger.) Caspary, W. F.; Kausch, H. (Med. Univ.-Klinik und Poliklinik, Humboldtallee 1, 34 Gottingen, W. Germany). *Fortschr. Med.* 95(31):1931-1939; 1977.

The effect of a liquid antacid (Gastropulgit gel: attapulgit + aluminum hydroxide and magnesium carbonate) on the transmural electrical potential difference (TEPD) of the gastric mucosa (potential difference between serosa and mucosa) was studied in healthy young adults following intragastric administration of 640 mg acetylsalicylic acid (ASA) in 50 ml of a 0.9% common salt solution. ASA alone decreased the TEPD from 44.27 ± 5.38 mV to 28.27 ± 8.14 mV ($p<0.001$), and this value did not return to normal during the first 30 min after ASA administration. When the same dose of ASA was administered with 20 ml of Gastropulgit gel, the ensuing drop in the TEPD was not statistically significant (from 39.85 ± 4.87 mV to 34.14 ± 4.85 mV; $p>0.05$). Since the TEPD is correlated with several functional parameters of the gastric mucosal barrier, Gastropulgit gel appears to exert a protective effect against the acute damage to the gastric mucosa caused by salicylates.

7347 EFFECT OF 13-NLE-MOTILIN ON GASTRIC SECRETION, SERUM GASTRIN LEVEL AND MUCOSAL BLOOD FLOW IN DOGS. (Eng.) Konturek, S. J.; Dembinski, A.; Krol, R.; Wunsch, E. (Medical Acad., Krakow, Poland). *J. Physiol. (Lond.)* 264(3):665-672; 1977.

The effects of 13-norleucine-motilin (13-nle-motilin) on basal gastric acid and pepsin secretion, serum gastrin level, pentagastrin-induced gastric secretion, histamine-induced gastric secretion, and mucosal blood flow were investigated in dogs prepared with chronic gastric fistulas and denervated fundic and antral pouches. 13-Nle-motilin infused i.v. in graded doses (1.5-100 ng/kg/hr) produced a dose-dependent increase in gastric acid and pepsin outputs, corresponding at their peaks to about 25% and 3% of the maximal response to pentagastrin (8 μg/kg/hr), resp.; these peaks occurred at the 50 μg/kg/hr dose of 13-nle-motilin. The motilin-induced stimulation of gastric secretion occurred independently of antral pH and was not accompanied by any alteration in the serum gastrin level, suggesting that motilin did not affect the release of gastrin. When infused i.v. in a constant dose against a constant background stimulation with pentagastrin or histamine, 13-nle-motilin inhibited both acid and pepsin secretion from the main stomach and fundic pouch. The inhibitory effect of 13-nle-motilin was always associated with a marked reduction in mucosal blood flow but without any change in the ratio of aminopyrine concentration in the gastric juice and blood plasma, indicating that this peptide primarily affects gastric secretion but does not limit the gastric mucosal microcirculation.

7348 EFFECT OF NICOTINE ON GASTRIC ACID SECRETION: EVIDENCE OF ELECTROGENIC PUMP THEORY. (Eng.) Dinno, M. A.; Ando, M.; Dinno, F. H.; Huang, K. C.; Rehm, W. S. (Dept. Pharmacology, Univ. Louisville, Louisville, KY 40201). *Am. J. Physiol.* 232(3):E251-E257; 1977.

The effect of nicotine on H^+ and Cl^- in the frog stomach was studied to determine the mechanism (unitary or electrogenic) involved. Nicotine (5 mM serosal bathing solution) reduced gastric acid secretion 90% and increased the transmucosal potential difference (PD) and short-circuit current (Isc) without changing the transmucosal resistance. A dose-response correlation was shown. During the first 8 min, the changes in the measured parameters, namely, PD versus H^+ secretory rate (I_H) and Isc versus I_H, were linear. After 8 min, there was a deviation from linearity. Isotopic ^{36}Cl flux measurement across the gastric mucosa under the short-circuit condition showed that the serosal-to-mucosal flux of Cl^- was greater than the mucosal-to-serosal flux, resulting in a net Cl^- secretion. Thus, 5 mM nicotine caused only a 41% reduction in net Cl^- secretion. The linear relationships between PD versus I_H and Isc versus I_H lend support to the electrogenic theory of HCl secretion.

7349 OCCURRENCE OF GASTRIN IN GASTRIC JUICE, IN ANTRAL SECRETION, AND IN ANTRAL PERFUSATES OF CATS. (Eng.) Uvnas-Wallensten, K. (Dept. Pharmacology, Karolinska institutet, S-104 01 Stockholm 60, Sweden). *Gastroenterology* 73(3):487-491; 1977.

To determine whether the gastrin found in the gastric juice of cats reaches the gastric lumen via the corporeal or via the antral mucosa, cats underwent insertion of a cannula into the corporeal wall halfway between the cardia and the antrum-corpus boundary. Gastric juice secretion was induced by electrical vagal stimulation. For gastrin determinations, gastric juice samples were collected every 7.5 or 15 min and neutralized immediately, and the acidity was determined by titration with 0.01 M NaOH. When an acute antral pouch was created by ligation of the gastric lumen, most of the gastrin was found in the antral secretion. When the antral pouch was perfused with a warm phosphate buffer solution, the amount of gastrin appearing in the antral perfusate was significantly greater than that in the gastric venous effluent (the antrum: blood release ratio ranged from 2 to 23, average 10.5). Electrical stimulation of the vagi increased gastrin output into the antrum and the circulation.

7350 CYCLIC AMP AND THE RELEASE OF ANTRAL GASTRIN. (Eng.) Gabrys-Pomykala, B. F.; Alavi, S. M.; Nyhus, L. M.; Bombeck, C. T. (Univ. Illinois Medical Center, Chicago, IL). *Scand. J. Gastroenterol.* 12(4):507-511; 1977.

To investigate the possible role of cyclic AMP in the release of antral gastrin, the cyclic AMP content in the canine antral mucosa and the antral venous immunoassayable gastrin levels were determined. The isolated, vagally innervated antral pouches in anesthetized dogs were irrigated with 0.5% acetylcholine chloride (Ach) or a 0.4 M mixture of nonessential amino acids (AA), or distended at 30 cm H_2O. In addition, 2-deoxy-D-glucose (2-DG, 100 mg/kg) was administered i.v. Significant increases in antral venous gastrin, caused by gastrin releasers, were associated with a significant rise in cyclic AMP content in the antral mucosa. Acidification of the antrum with simultaneous administration of 2-DG and acidified AA abolished gastrin release, and significantly reduced mucosal cyclic AMP. Acidified Ach and distention of the antrum with 0.1 N HCl suppressed gastrin levels without significantly changing the mucosal cyclic AMP content. Since the augmented gastrin release was accompanied by an increased mucosal cyclic AMP, the results suggest that cyclic AMP participates in the action of gastrin secretagogues.

7351 GLYCOLIPIDS OF THE HUMAN GASTRIC CONTENT: STRUCTURE OF THE SULFATED GLYCEROGLUCOLIPID. (Eng.) Slomiany, B. L.; Slomiany, A.; Glass, G. B. J. (New York Medical Coll., 5th Ave at 106th St., New York, NY 10029). *Eur. J. Biochem.* 78(1):33-39; 1977.

The characterization of a new sulfated glycolipid isolated from the lipid extract of human gastric content is described. The isolation procedure involved column fractionation on silicic acid and thin-layer chromatography. Degradation studies revealed the presence of glucose, sulfate, fatty acids, and glyceryl monoethers. The structure of this glycolipid was identified by partial acid hydrolysis, oxidation with periodate and chromium trioxide, and permethylation studies as: SO_3H-6Glcα1→6Glcα1→6Glcα1→3-diglyceride. The diglyceride portion of this glycolipid consists mostly of 1-*O*-alkyl-2-*O*-acyl-glycerol.

7352 GLYCOPROTEIN TRANSPORT IN THE SURFACE MUCOUS CELLS OF THE RAT STOMACH. (Eng.) Kramer, M. F.; Geuze, J. J. (Sch. Medicine, Univ. Utrecht, Utrecht-2501, Netherlands). *J. Cell. Biol.* 73(3):533-547; 1977.

The intracellular transport of glycoproteins pulse-labeled *in vitro* with tritiated leucine and galactose was studied in the surface mucous lining cells (SMC) of the rat fundic stomach by electron microscope autoradiography. The SMC survived for several hours in pieces of the fundus incubated in a bicarbonate-buffered medium. The SMC had a normal ultrastructure for at least 4 hr of incubation. Kinetic activity was normal for at least 5 hr as demonstrated by the normal nuclear incorporation of tritiated thymidine. The SMC incorporated labeled leucine and galactose at normal rates up to 4 hr and 6 hr, resp. In contrast to the SMC, the cells of the gastric glands showed signs of degeneration within 1 hr after the start of incubation. In the SMC, the secretory protein formed a smaller part of the total protein synthesized than in other secretory cells studied. The intracellular transport of the leucine-labeled moiety of the glycoproteins followed the normal pathway. The RER lost 35% of its transportable labeled protein within 30 min. The Golgi complex was maximally labeled at 40 min and the mucous granules after 120 min. Galactose was attached to the glycoproteins mainly in the Golgi complex. Glycoproteins were not secreted within 2 hr after synthesis of their protein moiety.

7353 COMPARISON BETWEEN TRUNCAL AND SELECTIVE GASTRIC VAGOTOMY IN RATS. (Ger.) Schwamberger, K.; Geir, W. (Geriatrisch-chirurgische Univ.-Klinik Innsbruck, Anichstrasse 35, A-6020 Innsbruck, Austria). *Langenbecks Arch. Chir.* 344(1):53-60; 1977.

The effects of truncal and selective vagotomy were studied in adult Sprague-Dawley rats after pyloric ligation according to Shay for 9 hr. There were no significant differences between the two procedures with respect to gastric tonicity, gastric acid secretion (ml/100 g body weight), gastric juice pH, and total acidity (in mEq HCl per 100 g). Both forms of vagotomy protected the animals from stress ulcer, but truncal vagotomy was more efficient. The size of the stress ulcers was 0-1 mm^2 following truncal vagotomy, 1-2 mm^2 following selective vagotomy, 0-1 mm^2 following truncal vagotomy with ligation of the left gastric artery, and 1-2 mm^2 following simultaneous truncal and selective vagotomy. The difference between selective and truncal vagotomy in terms of the size of the stress ulcer is statistically significant ($p=0.05$). This difference is due to devascularization of the lesser curvature of the stomach.

7366 PHOTOAFFINITY LABELING OF A PEPTIDE SECRETAGOGUE RECEPTOR IN THE EXOCRINE PANCREAS. (Eng.) Galardy, R. E.; Jamieson, J. D. (Yale Univ. Sch. Medicine, New Haven, CT 06150). *Mol. Pharmacol.* 13(5):852-863; 1977.

The feasibility of photoaffinity labeling receptors for 2-nitro-5-azidobenzoyl-Gly-Trp-Met-Asp-Phe-NH_2 (NAB-CCK-5) in lobules (small clusters of acini) of guinea pig pancreas was studied. NAB-CCK-5 mimics cholecystokinin and the more potent secretagogue cerulein in stimulating the discharge of exportable proteins from acinar cells of the guinea pig pancreas *in vitro*. Photolysis of this affinity label (5 μM) causes irreversible stimulation of a protein discharge that is indistinguishable in rate, magnitude, and morphological aspects from that observed with the most potent doses of cerulein (0.1 mM). The irreversible agonist activity cannot be removed by extensive washing of the lobules, and it is blocked only by metabolic inhibition (by performing the 3-hr assay at 0 C or under 95% nitrogen-5% carbon dioxide atmosphere, or in the presence of an uncoupler of oxidative phosphorylation). Irreversible agonist activity is not observed without photolysis, and it is not observed after photolysis of lobules in the presence of 2-nitro-5-azidobenzoic acid, 2-nitro-5-azidobenzoyl-angiotensin II, 2-nitro-5-azidobenzoyl-Gly-Gly-Met-Asp-Phe-NH_2, cerulein, or with previously photolyzed NAB-CCK-5. However, protection by native peptide secretagogues against irreversible labeling by NAB-CCK-5 was not shown. The labeled biologically active sites appear to be those responsible for peptide secretagogue-mediated release of exportable proteins. The mechanism of labeling NAB-CCK-5 is not clear, since native secretagogues show no competition for labeling.

7367 HISTOCHEMICAL STUDY OF CHOLINERGIC ACTIVITIES IN EXOCRINE PANCREAS OF DOGS: MODIFICATIONS RELATED TO CHRONIC ALCOHOLISM.

(Eng.) Celener, D.; de la Porte, P. L.; Tiscornia, O.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM U 31, 46, Chemin de la Gaye, 13009 Marseille, France). *Biomedicine* 27(4):161-165; 1977.

The effect of alcoholism on cholinergic activity in the canine exocrine pancreas was histochemically examined from pancreatic biopsies obtained from five adult mongrel dogs provided with duodenal and gastric cannulae that received a standard diet enriched in fat and protein. Three of the dogs received 2.0 g/kg/day of ethanol diluted in isotonic saline through the gastric cannula over periods of 3, 4, and 48 months, resp. The other two dogs served as controls. In the two nonalcoholic dogs, the localization of acetylcholinesterase (AChE) activity in the exocrine pancreas fit the classical description. Nerve fibers entered along the connective septa as discrete bundles of perivascular plexuses and passed to the glandular tissue. Fine fibrils ran to acinar zones and formed a periacinar nerve network. In dogs receiving ethanol for 3 and 4 months, resp., there were many interlobular and perivascular fibers, but the branching was less conspicuous and the number of fine periacinar fibrils, as well as their enzyme activity, was decreased compared with controls. Decreased AChE activity in dogs receiving ethanol for 48 months was more pronounced and was limited to the fine fibrils. Choline acetyl transferase (CAT) activity was low in nonalcoholic dogs and was localized on the periacinar fibrils that formed a delicate framework. In dogs receiving ethanol for 3 and 4 months, resp., CAT activity was increased compared with that of control dogs. Although the CAT distribution was similar to that of controls, the fibrils appeared darker and enlarged. Sometimes the fibrils appeared to be reduplicated, and many had a perivascular location. In dogs receiving ethanol for 48 months, a striking increase in CAT activity was seen in spite of some nonspecific metal deposit on the secretory granules of the acinar cells. Although the histochemical observations were only semiquantitative, the results suggest that the cholinergic tone of the exocrine pancreas is increased in chronic alcoholic dogs.

7368 CANINE EXOCRINE PANCREATIC SECRETORY CHANGES INDUCED BY AN INTRAGASTRIC ETHANOL TEST MEAL.

(Eng.) Tiscornia, O. M.; Levesque, D.; Sarles, H.; Bretholz, A.; Voirol, M.; De Oliveira, J. P. M.; *et al.* (Sch. Medicine of Buenos Aires, Buenos Aires, Argentina). *Am. J. Gastroenterol.* 67(2):121-130; 1977.

Exocrine pancreatic secretory changes induced by an intragastric ethanol test meal were studied in five dogs with chronic gastric fistulas (Thomas cannula) and a new type of chronic pancreatic fistula that permits the collection of pure nonactivated pancreatic juice after the ingestion of a test meal. In the first series of experiments, a test meal (400 g canned dog meat) was given with 200 ml saline simultaneously infused through the gastric cannula. In response to this stimulus, the 20-min peak pancreatic flow rate and bicarbonate output were 33% and 34%, resp., of the maximal secretion of the pancreatic gland obtained with secretin in six control dogs provided with gastric and the classical Thomas duodenal fistula. The 20-min peak protein output represented 84% of the maximal secretory capacity attained with dose-response curves to cholecystokinin in the same group of control animals. In the second series, either 1.5 or 2.0 g/kg ethanol were given instead of saline. Intragastric ethanol induced a dissociation of pancreatic secretion. Ethanol also induced a significant inhibition of flow rate, of bicarbonate concentration, and of bicarbonate output, and it caused a significant rise in protein concentration. The protein output remained unchanged. It is postulated that ethanol, acting on the stomach, duodenum, and jejunum, evokes, independently of its gastrin-releasing capacity, an unknown humoral or nervous mechanism that counteracts the ethanol-elicited cholinergic-mediated inhibition of pancreatic protein secretion.

7369 THE EFFECT OF SYMPATHOMIMETIC DRUGS ON EXOCRINE PANCREAS FUNCTION. STUDIES IN THE ISOLATED CAT PANCREAS.

(Ger.) Heidbreder, E.; Sieber, P.; Heidland, A. (Medizinische Universitatsklinik Wurzburg, Josef-Schneider-Strasse 2, D-8700 Wurzburg, W. Germany). *Res. Exp. Med.* 171(1):79-92; 1977.

The effects of perfusion of various sympathomimetic drugs on α-amylase, lipase, protein, and Ca secretion into the pancreatic juice and on the rate of volume output were studied in the isolated pancreas of adult cats. Pancreatic juice flow was stimulated by secretin, and enzyme secretion was stimulated by acetylcholine (AC, 100 ng) or cholecystokinin-pancreozymin (0.1-0.2 U). Isoproterenol, metaproterenol, salbutamol, fenoterol, and terbutaline stimulated protein and enzyme secretion and caused a transient, slight reduction of the volume output of pancreatic juice. Phentolamine and phenoxybenzamine did not influence basal pancreatic secretion, but they inhibited AC-stimulated protein secretion. β-Adrenolytic drugs did not affect volume output or Ca, chloride, nonstimulated protein, and enzyme secretion. AC-stimulated protein secretion was inhibited by D-propranolol, prindolol, oxprenolol, practolol, and butoxamine. β-Sympathomimetics reduced protein and enzyme secretion that had been stimulated by β-adrenolytics, but D- and L-propranolol did not inhibit the effect of isoproterenol. Protein and enzyme secretion was stimulated by isoproterenol and salbutamol in cats pretreated with reserpine (1-1.5 mg/kg i.v.) before perfusion and by AC and β-sympathomimetics in cats pretreated with 6-hydroxydopamine (60 mg/kg i.v.). Tetracaine inhibited enzyme secretion following administration of β-sympathomimetics. Ca-free perfusion did not reduce the enzyme secretion induced by isoproterenol, salbutamol, and terbutaline, but pancreatic Ca secretion ceased after a 60-min perfusion. Nifedipine inhibited the AC effect during Ca-free perfusion. Hemicholinium markedly inhibited isoproterenol-stimulated protein and enzyme secretion without influencing volume output. Atropine caused reversible inhibition of the pancreatic output following the application of β-sympathomimetics without influencing volume output. The findings show that β-sympathomimetics have a cholinergic effect on pancreatic protein and enzyme secretion.

7370 EFFECTS OF MEMBRANE STABILIZERS ON PANCREATIC AMYLASE RELEASE. (Eng.) Williams, J. A.; Poulsen, J. H.; Lee, M. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *J. Membr. Biol.* 33(1/2):185-195; 1977.

The ability of compounds with membrane stabilizing activity to affect pancreatic amylase release was studied in male mice, and the steps in the stimulus-secretion coupling process were examined. Chlorpromazine, propranolol, and thymol (10^{-5}-10^{-4}, 10^{-4}-10^{-3}, and 10^{-4}-10^{-3} M, resp.) were all found to inhibit bethanechol-stimulated amylase release and, at slightly higher concentrations (3 x 10^{-4}, 3 x 10^{-3}, and 3 x 10^{-3} M, resp.), to induce release regardless of the presence of the secretagogue. This biphasic effect was similar to that found previously for the local anesthetic tetracaine. Release by high concentrations of propranolol and tetracaine was accompanied by ultrastructural evidence of cell damage. Membrane stabilizers at concentrations that inhibited amylase release were shown to block bethanechol-induced depolarization and stimulation of $^{45}Ca^{++}$ efflux, although the drugs alone partially depolarized pancreatic cells. The release of amylase induced by Ca^{++} (introduced by the ionophore A23187) was also abolished. There findings indicate that membrane stabilizers independently inhibit the steps leading to a rise in intracellular Ca^{++} and the subsequent Ca^{++}-activated amylase release.

7371 BIOCHEMICAL REACTIONS INVOLVED IN PANCREATIC ENZYME SECRETION. 4. EFFECTS OF CYTOCHALASIN B ON FUNCTIONS OF THE EXOCRINE PANCREAS. (Eng.) Morisset, J.; Beaudoin, A. R. (Departement de biologie, Universite de Sherbrooke, Sherbrooke, Quebec, Canada J1K 2R1). *Can. J. Physiol. Pharmacol.* 55(3):644-651; 1977.

The effects of cytochalasin B on pancreatic enzyme secretion were studied in an attempt to establish a role for microfilaments in the exocytosis process. Cytochalasin B (1 μg/ml) inhibited amylase secretion induced by urecholine or cholecystokinin-pancreozymin (CCK-PZ) but did not modify that induced by dibutyryl cyclic AMP. The inhibitory effect of the drug was reversible after a 30-min washing out period. It did not affect O_2 consumption, basal calcium efflux, or efflux caused by CCK-PZ. Amino acid accumulation in the tissue and their incorporation into proteins were not modified. It is suggested that cytochalasin B inhibits pancreatic enzyme secretion, probably through an effect on the microfilament system.

7372 EFFECTS OF Na PENTOBARBITAL ANESTHESIA ON SERUM SECRETIN AND EXOCRINE PANCREATIC SECRETIONS. (Eng.) Boden, G.; Shore, L. S.; Wilson, R. M.; Essa-Koumar, N.; Landor, J. H. (Temple Univ. Health Sciences Center, 3401 N. Broad St., Philadelphia, PA 19140). *Horm. Metab. Res.* 9(2):123-127; 1977.

The effect of sodium pentobarbital anesthesia on serum secretin concentration and exocrine pancreatic secretion was investigated in dogs with chronic gastric and pancreatic fistulas. Sodium pentobarbital anesthesia (30 mg/kg, i.v.) reduced basal pancreatic flow rate by 74%, bicarbonate by 70% and protein secretions by 81% without affecting basal immunoreactive secretin (IRS) concentration. The anesthesia had no effect on HCl (9.6 mEq/30 min, intraduodenally)-mediated IRS release, but it reduced HCl-mediated bicarbonate output by about 50%. It had no effect on pancreatic responsiveness to stimulation by exogenous secretin (0.5 IU/kg/30 min), and it did not affect serum concentrations of IRS following secretin infusion. These data suggest that basal pancreatic secretory functions are under control of tonic neural influences, that Na pentobarbital anesthesia has no effect on IRS release but inhibits stimulated pancreatic bicarbonate secretion through suppression of an unidentified agent, and that Na pentobarbital does not affect the metabolism of secretin. The intraduodenal administration of 9.6 mEq of HCl and the i.v. infusion of 0.5 IU/kg of secretin for 30 min both resulted in similar IRS concentrations of approximately 600 μU/ml (equivalent to 150 pg/ml).

7373 DIFFERENT ACTION OF HORMONAL STIMULATION ON THE BIOSYNTHESIS OF THREE PANCREATIC ENZYMES. (Eng.) Dagorn, J. C.; Mongeau, R. (Unite de Recherches de Pathologie Digestive, INSERM U 31, 46 chemin de la Gaye, 13009 Marseille, France). *Biochim. Biophys. Acta* 498(1):76-82; 1977.

The effect of hormonal stimulation on the synthesis of pancreatic protein and enzymes in Sprague-Dawley rats was investigated. The animals received an i.v. injection of either saline (controls) or cholecystokinin-pancreozymin (8 Ivy dog U/kg) together with secretin (5 clinical U/kg). Hormonal stimulation led to an immediate decrease in protein synthesis, followed by a sustained increase. Overall, the quantity of proteins synthesized by the pancreas within 60 min of stimulation was increased by 50% compared with controls. Pancreatic stimulation also resulted in nonparallel variations in the rates of biosynthesis of the pancreatic enzymes chymotrypsinogen, amylase, and lipase, suggesting independent regulation of these syntheses. When the result of one stimulation was calculated in terms of quantities of enzymes synthesized by the pancreas in comparison with controls, it was found that the quantities of chymotrypsinogen, amylase, and lipase were increased by 63, 26, and

10%, resp., in comparison with controls during the 60 min following hormonal injection. This result indicates that repeated cholecystokinin-pancreozymin plus secretin stimulations can induce adaptation-like modifications of the pancreatic enzyme content.

7374 PLASMA SECRETIN CONCENTRATION AND PANCREATIC EXOCRINE SECRETION AFTER INTRAVENOUS SECRETIN OR INTRADUODENAL HCl IN ANAESTHETIZED PIGS. (Eng.) Schaffalitzky de Muckadell, O. B.; Fahrenkrug, J.; Holst, J. J. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 12(3):267-272; 1977.

The concentration of immunoreactive secretin in arterial blood and in the exocrine pancreatic secretion were measured in female pigs (Danis Landrace breed) during the intraportal infusion of porcine secretin in doses of 0.03, 0.06, 0.1, 0.3, 1.0, and 3.0 clinical U (CU)/kg/hr and during the intraduodenal instillation of 50 ml 0.1 M HCl. The lowest dose of exogenous secretin to significantly increase secretin concentration in the blood was 0.03 CU/kg/hr, which was a subthreshold dose of exocrine pancreatic secretion. The infusion of 0.03 CU/kg/hr of exogenous secretin increased the plasma secretin concentration from 0.2 ± 0.2 pM to 3.1 ± 0.4 pM, which was more than twice the detection limit of the radioimmunoassay used. A linear relation was found between the secretin dose infused and the plasma secretin level, with the steady state plasma secretin concentration (in pM) being equal to 104 times the secretin dose (in CU/kg/hr) + 0.1. After the instillation of HCl, plasma secretin concentration reached a plateau slightly lower but not significantly different from the plateau reached during the infusion of 0.3 CU/kg/hr secretin, with the calculated release of secretin during HCl instillation being an estimated 0.22 CU/kg/hr. The lowest secretin dose giving a significant increase in pancreatic flow rate was 0.1 CU/kg/hr. Bicarbonate concentration in pancreatic juice, pancreatic flow rate, and bicarbonate output after stimulation with HCl were equal to values found during a 15-min period in which a secretin dose of 0.3 CU/kg/hr was infused and averaged 114 mM, 12 ml/hr, and 1.67 mmol/hr, resp. Maximum pancreatic flow rate and bicarbonate output required a secretin dose of 1.0 CU/kg/hr, whereas maximum bicarbonate concentration (141 mM) was reached at a secretin dose of 0.3 CU/kg/hr. It was not possible to demonstrate a significant effect of exogenous secretin infused into the portal vein at doses below 0.1 CU/kg/hr; thus, in the present model, measurement of secretin concentrations in plasma was a more sensitive and accurate method to demonstrate secretin release than determination of pancreatic bicarbonate output or flow rate.

7375 COMPARISON OF THE EFFECT OF SOMATOSTATIN ON GASTROINTESTINAL FUNCTION IN THE CONSCIOUS AND ANAESTHETIZED CAT AND ON THE ISOLATED CAT PANCREAS. (Eng.) Albinus, M.; Blair, E. L.; Case, R. M.; Coy, D. H.; Gomez-Pan, A.; Hirst, B. H.; *et al.* (Dept. Pharmacology, Univ. Tubingen, W. Germany). *J. Physiol. (Lond.)* 269(1):77-91; 1977.

The effects of somatostatin on pentagastrin-stimulated gastric secretion, on pancreatic electrolyte and enzyme secretion, on gallbladder function, and on gastric mucosal blood flow were studied in cats. Somatostatin (10 μg/kg/hr) inhibited gastric acid and pepsin secretion stimulated by pentagastrin (8 μg/kg/hr) in conscious and anesthetized cats with chronically implanted gastric fistulas. In the acutely surgically prepared anesthetized cat, somatostatin inhibited pepsin secretion but produced little inhibition of gastric acid secretion or mucosal blood flow. Secretin-stimulated pancreatic juice volume was not significantly reduced in acutely prepared anesthetized cats, but there was a limited reduction of cholecystokinin-pancreozymin stimulated pancreatic amylase secretion and gallbladder contraction. Somatostatin had neither stimulatory nor inhibitory effects on electrolyte and amylase secretion in the isolated saline-perfused cat pancreas. The results suggest that some of the effects of somatostatin may depend on the interaction of other factors (nervous or humoral) on the target cell and that these may vary in different experimental preparations.

7376 BLOCKING OF PROTEIN PANCREATIC SECRETION BY MAXIMAL SECRETIN INFUSION IN THE DOG. (Eng.) Tiscornia, O. M.; Lechene De La Porte, P.; Sarles, H. (Pozos 1916, 1245 Buenos Aires, C.F., Argentina). *Am. J. Gastroenterol.* 67(5):468-472; 1977.

7377 NUTRITIONAL AND CIRCADIAN VARIATIONS IN LIPASE ACTIVITY AND COLIPASE SATURATION IN RAT PANCREAS. (Eng.) Girard-Globa, A.; Simond-Cote, E. (Centre de Recherches sur la Nutrition, C.N.R.S., 92190 Meudon Bellevue, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):539-542; 1977.

7378 ELEVATED FECAL LEVELS OF ENDOGENOUS PANCREATIC ENDOPEPTIDASES AFTER ANTIBIOTIC TREATMENT. (Eng.) Borgstrom, A.; Genell, S.; Ohlsson, K. (Dept. Surg., Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 12(5):525-529; 1977.

7379 DECREASE OF NON-SUPPRESSIBLE INSULIN-LIKE ACTIVITY AFTER PANCREATECTOMY AND NORMALIZATION BY INSULIN THERAPY. (Eng.) Eigenmann, J. E.; Becker, M.; Kammermann, B.; Leemann, W.; Heimann, R.; Zapf, J.; Froesch, E. R. (Dept. Medicine, Univ. Zurich, Zurich, Switzerland). *Acta Endocrinol.* 85(4):818-822; 1977.

7380 THE EFFECT OF ACUTE HYPERGLYCAEMIA ON HORMONALLY STIMULATED PANCREATIC EXOCRINE SECRETION IN MAN. (Eng.) Clain, J.; Barbezat, G.

O.; Bank, S. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 52(9):358-361; 1977.

SECRETION AND METABOLISM

Hepatobiliary Tract

7382 AGE-RELATED CHANGES IN THE HEPATIC ENDOPLASMIC RETICULUM: A QUANTITATIVE ANALYSIS. (Eng.) Schmucker, D. L.; Mooney, J. S.; Jones, A. L. (Veterans Admin. Hosp., San Francisco, CA 94121). *Science* 197(4307):1005-1008; 1977.

A quantitative electron microscopic study of age-related changes in the hepatic endoplasmic reticulum of Fischer 344 rats was performed. The total endoplasmic reticulum in the centrilobular cells more than doubled in surface area in rats between 1 and 10 months of age ($p<.001$) from about 40 μm^2/average hepatocyte at 1 month to >80 μm^2/average hepatocyte at 10 months. The increase was less marked in the portal zone hepatocytes (65%, $p<.001$). At 20 months of age, the surface area of the total endoplasmic reticulum in both the centrilobular and portal zone hepatocytes was still increased over that observed in 1-month-old rats, but it was slightly less than that seen at 10 months of age. In 30-month-old rats, the specific surface area of the total endoplasmic reticulum had decreased for both zones of the liver lobule to values similar to those observed in 1-month-old rats. These changes were attributed to the smooth-surfaced endoplasmic reticulum, since neither the rough-surfaced endoplasmic reticulum nor the Golgi membranes underwent any significant change in surface area as a function of age.

7383 PREPARATION AND CHARACTERIZATION OF ISOLATED PARENCHYMAL CELLS FROM GUINEA PIG LIVER. (Eng.) Elliott, K. R.; Pogson, C. I. (Biological Lab., Univ. Kent, Canterbury, Kent CT2 NJ, England). *Mol. Cell. Biochem.* 16(1):23-29; 1977.

A method is described for the isolation and characterization of parenchymal cells from guinea pig liver. Dunkin-Hartley guinea pigs were anesthetized with i.p. nembutal (80 mg/kg) after fasting for 48 hr. Heparin (600 IU/kg) and bretylium tosylate (12.5 mg/kg) were added to the anesthetic solution to prevent vasoconstriction. The portal vein was clamped and cut on the hepatic side to permit liver perfusion through the inferior vena cava. After 20 min of perfusion with 200 ml of Ca^{2+}-free Krebs-Henseleit saline gassed with $O_2 + CO_2$ (95:5), the last 120 ml of which contained 0.03% collagenase, the liver was carefully removed. The liver cell suspension that resulted from washing with 0.9% NaCl and dispersion in 75 ml of medium containing Ca^{2+32} and 2% bovine serum albumin was filtered and centrifuged at 30 x *g* for 2 min. Washing and centrifugation were repeated, and a final suspension was prepared of 20 mg cells (dry weight)/ml Krebs-Henseleit medium containing 2% serum albumin. This preparation gave a cell yield of 20-30%. There was negligible loss of cytoplasmic enzymes as the gluconeogenesis and ureoneogenesis rates were within the physiological range.

7384 ISOLATED RAT LIVER NEEDS CALCIUM TO MAKE BILE. (Eng.) Owen, C. A., Jr. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Proc. Soc. Exp. Biol. Med.* 155(3):314-317; 1977.

The role of calcium in hepatic bile synthesis was studied in isolated Sprague Dawley rat livers. When normal livers were perfused with heparinized normal rat whole blood, 10-15 µl of bile were excreted per minute. This amount was reduced to one-tenth of its normal rate by the addition of 0.13 M sodium citrate to the blood. When 0.1 M calcium chloride was subsequently added, bile flow returned to normal if the interval between the additions of citrate and calcium did not exceed 1 hr. Magnesium chloride (0.1 M) had no such corrective effect. Two tests of liver function, generation of factor VII and conversion of [^{14}C]alanine to TCA-precipitable ^{14}C, were unaffected by the addition of citrate to plasma-free perfusions. Calcium is normally present in bile and might well be a necessary ingredient for the generation of bile.

7385 TIME-DEPENDENT ELIMINATION OF SUBSTRATES FLOWING THROUGH THE LIVER OR KIDNEY. (Eng.) Bass, L.; Bracken, A. J. (Dept. Mathematics, Univ. Queensland, Brisbane, Australia). *J. Theor. Biol.* 67(4):637-652; 1977.

Established steady-state models of elimination of flowing substrates by Michaelis-Menten kinetics in the intact liver and kidney are extended to time-dependent situations. The common features and differences of these models are presented. Time-dependent distributions of substrate concentration can be calculated with the use of steady-state results and a knowledge of the motion of fluid through the organs. The result is simplest when time-dependence is due to changes in substrate concentrations at the inlet, i.e., following injection or infusion. Flow through the liver is dealt in greater detail, and the instantaneous overall elimination rate, with special reference to galactose elimination, is evaluated for this organ.

7386 THE TRANSPORT, HEPATOBILIARY DISTRIBUTION AND CLEARANCE OF ^{99m}Tc-Sn-LIDOCAINE IMINODIACETIC ACID, ^{99m}Tc-Sn-LIDA. (Eng.) Noronha, O. P. D.; Sewatkar, A. B.; Ganatra, R. D.; Subramanian, G. (Tata Memorial Hosp., Parel, Bombay 400 012, India). *Int. J. Nucl. Med. Biol.* 4(2):122-128; 1977.

The method of preparation, transport, hepatobiliary distribution, and clearance of ^{99m}Tc-Sn-lidocaine iminodiacetic acid (^{99m}Tc-Sn-*lida*) was studied. Paper chromatography in citric acid-*n*-butanol showed that the radiopharmaceutical had a R_f=0.0 and any free ^{99m}Tc-O_4^- migrated with a R_f=0.30-0.35. Electrophoretic mobilities showed that it moves to about 3.0 cm towards the anode, whereas free $^{99m}TcO_4^-$ travels about 6-7 cm in veronal buffer system under the same conditions. These patterns of behavior were found to be stable for at least 4 months. Toxicity and survival studies in mice indicated that there were no untoward effects, even at a dose as high as 210 mg/kg. Tissue distribution studies in mice injected i.v. with 20 μCi of ^{99m}Tc-Sn-LIDA indicated that the liver activity decreased from about 28% at the end of 6 min to about 9% in about 20 min, followed by a concomitant increase in the gut activity from 40% to 75% in the corresponding time interval. There was negligible activity in other organs (spleen, lungs, thyroid). A similar behavior pattern was seen when the radiopharmaceutical was administered in rats. Scintiscans obtained in rabbits injected i.v. with 2.0 mCi of ^{99m}Tc-Sn-LIDA showed extremely rapid excretion into the gut. At 7 min, the liver was visualized, and clearance had already started at this time. At 30 min, the gallbladder was seen distinctly with a considerable portion of the activity cleared into the gut. In humans, liver uptake was also rapid, and gallbladder localization took place in about 20 min. ^{99m}Tc-Sn-LIDA behaves as an excellent hepatobiliary agent. It is rapidly cleared from the blood, preferentially localized in the hepatocytes, and cleared through the bile en route to the bowel. The ease of its preparation, its stability, and its low toxicity enhances its usefulness in nuclear medicine procedures.

7387 UNIDIRECTIONAL INFLUX OF GLUTAMINE AND OTHER NEUTRAL AMINO ACIDS INTO LIVER OF FED AND FASTED RAT IN VIVO. (Eng.) Pardridge, W. M. (Univ. California at Los Angeles Center for the Health Sciences, Los Angeles, CA 90024). *Am. J. Physiol.* 232(5):E492-E496; 1977.

The fractional extraction of the unidirectional influx of several neutral amino acids (glutamine, leucine, alanine, tryptophan, and cycloleucine) into rat liver *in vivo* was studied with a tissue-sampling, single-injection technique. Liver uptake of ^{14}C-amino acid was expressed as an index relative to the hepatic clearance of a ^{3}H-labeled water (^{3}HOH) internal reference. The maximal fractional extraction of ^{3}HOH influx into liver (0.85) and the rate constant of ^{3}HOH efflux back to blood (0.87/min) provided an estimate of portal blood flow, 0.93 ml/min/g, in the barbiturate-anesthetized, laparotomized rat. Given the extraction data for the ^{3}HOH reference, liver uptake indices for the five amino acids studied were converted into maximal fractional extractions of amino acid influx into liver: glutamine, 0.72 ± 0.03; leucine, 0.56 ± 0.02; alanine, 0.43 ± 0.04; tryptophan, 0.40 ± 0.03; cycloleucine, 0.25 ± 0.01; and sucrose, 0.09 ± 0.02. The influx of glutamine and cycloleucine was shown to be increased 35% with 48 hr of fasting. These data indicate that glutamine penetrates the liver cell membrane faster than any of the 19 amino acids studied thus far. The rate of unidirectional influx of glutamine and other amino acids into liver reveals that the capacity of liver cells to transport amino acids is several fold greater than that of other organs such as brain or muscle.

7388 GALLBLADDER BILE COMPOSITION IN DIFFERENT ETHNIC GROUPS. (Eng.) Oviedo, M. A.; Ho, K. J.; Biss, K.; Soong, S. J.; Mikkelson, B.; Taylor, C. B. (Cancer Center, Northwestern Univ., Chicago, IL). *Arch. Pathol. Lab. Med.* 101(4):208-212; 1977.

One hundred and ninety-four gallbladder biles from various ethnic groups were analyzed for their composition. The subjects included 64 white patients without gallstones, 93 white patients with gallstones, and 37 black patients without gallstones. The solubility of cholesterol in bile was determined mainly by the relative amounts of phospholipid and bile salt present. Bile from patients with gallstones was usually supersaturated with cholesterol above the boundary of the metastable state. Biles from normal white subjects of Finland, New Zealand, and the United States were already in the metastable state of supersaturation with cholesterol. The Masai of East Africa and black subjects of the United States had a bile level below the limit of maximum cholesterol solubility. This study indicates that the difference in the prevalence of cholesterol cholelithiasis in various ethnic groups is related to the difference in their bile composition, which might, in turn, be controlled by some genetic and other as yet unidentified factors.

7389 PROLONGED INDUCTION OF GERMFREE BILE ACID PATTERN IN CONVENTIONAL RATS BY ANTI-

BIOTICS. (Eng.) Gustafsson, B. E.; Gustafsson, J. A.; Carlstedt-Duke, B. (Dept. Germfree Res., Karolinska Institutet Stockholm, Sweden). *Acta Med. Scand.* 201(4):155-160; 1977.

To determine the effects of antibiotics on the bile acid pattern in the intestinal contents of conventional rats, male AGUS rats reared under germfree conditions were given benzylpenicillin (360,000 IU/kg/day), neomycin (180 mg/kg/day), kanamycin (35 mg/kg/day), erythromycin (360 mg/kg/day), bacitracin + neomycin (27,000 IU/kg/day and 550 mg/kg/day, resp.), succinylsulfathiazole (360 mg/kg/day), and metronidazole (20 or 100 mg/kg/day). The animals received the drugs through a stomach tube for 5 days. Feces were collected daily for 3 days, followed by a 4-day interval between each collection period, and the total fecal bile acids in each sample were assessed by gas chromatography. Eight weeks after the initiation of treatment, rats were given an enema with 1 ml of a 10^{-1} dilution of cecum contents from six intact syngeneic rats. The characteristic features of the pretreatment bile acid pattern were the presence of allodeoxycholic acid, deoxycholic acid, β-muricholic acid, hyodeoxycholic acid, and allohyodeoxycholic acid. Treatment with antibiotics resulted in a germfree pattern (disappearance of allo-, hyo-, and deoxycholic acids and appearance of α-muri-, chenodeoxy-, and cholic acids) that was not normalized until the normal intestinal flora was reestablished by the intestinal bacteria-containing enema.

7390 BILE-FAT RELATIONSHIPS IN GASTRIC SECRETORY INHIBITION AND BILE FLOW STIMULATION. (Eng.) Kihl, B. O.; Boden, G.; Landor, J. H. (CMDNJ-Rutgers Medical Sch., Piscataway, NJ 08854). *Surgery* 81(4):386-391; 1977.

To clarify the possible role of bile in fat-induced gastric secretory inhibition, the effect of intraduodenal infusion of mineral oil, olive oil, bile, or a mixture of olive oil and bile on pentagastrin-stimulated gastric secretion, bile flow, and serum immunoreactive secretin levels was studied in dogs. Mineral oil alone or bile alone had no effect on gastric secretion; olive oil alone caused an insignificant diminution of gastric secretion, but the mixture of bile and olive oil induced prompt, statistically significant gastric secretory inhibition ($p<0.001$). Bile had the early choleretic effect that would be expected to result from the absorption of bile salts; olive oil alone caused a delayed (by 45-60 min) increase in bile flow, whereas the bile-olive oil mixture brought about a delayed and much greater increase in bile flow rates; the mean bile secretion was 2.3 cm^3/15 min after olive oil and 3.3 cm^3/15 min after olive oil plus bile. None of the agents given intraduodenally produced a significant change in the serum secretin level. Intravenous pentagastrin infusion caused a significant increase in rate of bile flow ($p<0.001$). The results offer further evidence that fat, in the presence of bile, acts as a potent inhibitor of gastric acid secretion.

7391 GAS-LIQUID CHROMATOGRAPHIC ASSAY OF SERUM BILE ACIDS. (Eng.) Ross, P. E.; Pennington, C. R.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee DD1 9SY, Scotland). *Anal. Biochem.* 80(2):458-465; 1977.

The analysis of serum bile acids by gas-liquid chromatography is described. Bile acids are extracted from 0.5-2 ml of serum and analyzed as methyl ester trifluoroacetates following enzymatic hydrolysis of the taurine and glycine conjugates. The method does not detect bile acid sulfates, although inclusion of a solvolysis procedure before enzymatic hydrolysis would allow for their measurement. The method was used to establish normal values for serum bile acids in normal subjects after an overnight fast and 2 hr postprandially (p.p.). After the overnight fast, mean levels of lithocholic acid, deoxycholic acid, chenodeoxycholic acid (CDCA), ursodeoxycholic acid, and cholic acid were 0.09, 0.47, 0.88, 0.05, and 0.60 μM, resp.; mean levels 2 hr p.p. were 0.18, 0.59, 1.39, 0.13, and 0.98 μM, resp. Thus, in normal subjects, the main serum bile acid was CDCA. The increase in total serum bile acids 2 hr p.o. (3.34 versus 2.07 μM after fasting) was mainly due to an increase in primary bile acids, since the other bile acids did not rise consistently. In two normal subjects, serum was collected during fasting and at 15-min intervals for 2 hr p.p. The bile acids, again mainly CDCA, increased after only 15 min. Peak levels were observed at 75 min p.p., after which they gradually fell; however, they were still elevated 2 hr p.p. Sera from liver disease patients contained substantially elevated levels of bile acids (both fasting and p.p.) with respect to healthy controls, indicating that the method can differentiate between normal and liver disease subjects.

7392 EFFECTS OF DIFFERENT BILE SALTS UPON THE COMPOSITION AND MORPHOLOGY OF A LIVER PLASMA MEMBRANE PREPARATION, DEOXYCHOLATE IS MORE MEMBRANE DAMAGING THAN CHOLATE AND ITS CONJUGATES. (Eng.) Vyvoda, O. S.; Coleman, R.; Holdsworth, G. (Dept. Biochemistry, Univ. Birmingham, P.O. Box 363, Birmingham B15 2TT, England). *Biochim. Biophys. Acta* 465(1):68-76; 1977.

The effects of various bile salts on rat liver plasma membrane preparations were studied. Plasma membrane preparations were incubated with various bile salts at 0 or 37 C. The bile salts caused the removal of various amounts of proteins, membrane enzymes, and phospholipids. Cholate, taurocholate, and glycocholate removed appreciable amounts of protein from the saline-washed membranes, and considerable amounts of both phospholipids and the membrane enzymes, 5-nucleotidase, alkaline phosphatase, alkaline phosphodiesterase 1, and L-leucyl-β-naphthylamidase. These losses were greater at 37 than at 0 C. The material remaining contained membrane-like profiles, many of vesicular form, even when the preparation was almost completely devoid of phospholipids. Deoxycholate, both at 0 and 37 C, removed more protein, membrane enzymes, and phospholipids than did cholate and its conjugates. The material remaining was mainly granular and unorganized, and the only remaining features were structures resembling the nexus, and occasional desmosomes. Deoxycholate appears to cause greater perturbation of membrane structure than the trihydroxy bile salt, cholate, and its conjugates. The results may have implications for the effects of bile salts upon the membranes of liver cells during bile salt secretion and the production of bile.

7393 QUANTITATIVE DETERMINATION OF SERUM BILE ACIDS USING A 7α-HYDROXYSTEROID DEHYDROGENASE. (Eng.) Fausa, O.; Skalhegg, B. A. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(4):441-447; 1977.

Primary bile acids in serum from healthy volunteers and from patients with parenchymatous liver disease or cholestatic hepatobiliary disorders were measured by an enzymatic-fluorimetric method that utilizes a crude 7α-hydroxysteroid dehydrogenase isolated from *P. testosteroni*. The mean recovery of cholic and chenodeoxycholic acids averaged 85.5 ± 5.7% from normal sera and 84.5 ± 6.3% from jaundiced sera. The mean concentration of serum 7α-hydroxy bile acids (primary bile acids) in fasting, healthy subjects was 2.5 ± 1.45 µM (range, 1.2-6.3 µM); this comprised 73 ± 11.5% of the total bile acid concentration (measured as the 3α-hydroxy bile acid concentration). In the cholestatic hepatobiliary disease and parenchymatous liver disease patients, the proportion of 7α-hydroxy bile acids (with respect to total bile acids) was significantly ($p < 0.001$) increased, with mean values of 91.5 ± 8.0% and 93.5 ± 9.6%, resp., being observed. The enzymatic-fluorimetric procedure was reliable and sensitive; when used in conjunction with 3α-hydroxysteroid dehydrogenase, it enabled the concentration of primary and secondary bile acids to be determined directly.

7394 COMPARATIVE STUDIES OF THE EFFECTS OF FASTING ON BILE SALT POOL SIZES OF HAMSTERS AND RATS. (Eng.) Beher, W. T.; Stradnieks, S.; Lin, G. J.; Konde, W. L. (Henry B. Ford Hosp., 2799 W. Grand Blvd., Detroit, MI 48202). *Steroids* 29(5):695-700; 1977.

The effect of fasting on total bile salt pool size was measured and compared in cholecystectomized and intact Syrian hamsters and in a species of rat that lacks a gallbladder. Bile salts were measured in the liver and bile ducts, cecum, small intestine, and, when present, gallbladder of animals that had been fed normally or fasted for 24, 48, or 72 hr. The rats maintained the size of their total bile salt pool during the fast periods possibly due to the continuation of enterohepatic circulation during fasting. Consequently, the bile salt concentration in the rat liver would not increase and bile acid biosynthesis would continue, thereby maintaining the bile salt pool size. Intact hamsters maintained and even increased their bile salts during fasts by storing the salts in the gallbladder and, to some extent, the small intestine When the hamsters were cholecystectomized, the total bile salt pool of animals fasted for 48 hr decreased to about one-third the level of animals on a normal diet (7.37 ± 2.33 µM/100 g versus 21.6 ± 2.20 µM/100 g; $p<0.01$).

7395 DIFFUSION COEFFICIENTS OF SINGLE BILE SALT AND BILE SALT-MIXED LIPID MICELLES IN AQUEOUS SOLUTION MEASURED BY QUASIELASTIC LASER LIGHT SCATTERING. (Eng.) Oh, S. Y.; McDonnell, M. E.; Holzbach, R. T.; Jamieson, A. M. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Biochim. Biophys. Acta* 488(1):25-35; 1977.

Diffusion coefficients of single bile salt micelles and bile salt-mixed lipid micelles in aqueous solution were measured by quasielastic laser light scattering. There was a negligible change in the micellar translational diffusion coefficient (D_t) with bile salt concentration in most bile salt systems except in taurodeoxycholate systems with and without added phosphatidylcholine (PTC) and in ternary systems (bile salt-PTC-cholesterol) that were saturated or metastably supersaturated with respect to cholesterol. D_t values extrapolated to zero micelle concentration D_t^0 for the pure bile salt conjugates sodium glycocholate, sodium glycodeoxycholate, sodium taurochenodeoxycholate and mixed bile salt micelles of the Neiderheiser-Roth composition were (x 10^6 cm^2/sec): 1.75, 1.50, 1.46, 1.57, 1.22, 1.02, and 1.67, resp. The Stokes radii for these pure bile salt conjugates were 18.8, 21.9, 22.5, 20.9, 26.9, 32.2, and 19.7 A, resp. Micellar size correlated with bile salt molecular structure. For binary systems containing the above single bile salts plus PCT (molar ratio=3:1), the corresponding D_t^0 values (given in the same order as above) were 1.60, 1.38, 1.07, 1.54, 1.23, and 0.93, resp. The Stokes radii for these binary micelles were 20.5, 23.8, 30.7, 21.3, 26.7, and 35.3 A, resp. In most systems, PTC produced a small increase in micellar size that is interpreted as simple swelling of the single-species micelles. The Stokes radii for ternary systems (bile salt-PTC-cholesterol) that were saturated or metastably supersaturated with respect to cholesterol were the same within experimental error, being 34.9 and 34.2 A, resp. The corresponding values of D_t^0 in these two ternary systems were 0.94 and 0.94, resp. It is concluded that intermicellar interactions significantly contributed to the measured diffusion coefficients in the ternary systems as well as in the single sodium taurodeoxycholate and the binary taurodeoxycholate-PTC systems over the bile salt concentration range (0-20% weight/volume) studied.

7396 STEROL AND BILE ACID METABOLISM DURING DEVELOPMENT. 1. STUDIES ON THE GALLBLADDER AND INTESTINAL BILE ACIDS OF NEWBORN AND FETAL RABBITS. (Eng.) Subbiah, M. T. R.; Marai, L.; Dinh, D. M.; Penner, J. W. (Mayo Clinic, Rochester, MN 55901). *Steroids* 29(1):83-92; 1977.

The content and distribution of bile acids in 26-day-old rabbit fetuses and 1-day-old newborn rabbits were studied. The intestinal tract and gallbladder were removed, and the extracted bile acids were subjected to gas-liquid chromatography. The bile acids of adult rabbits are predominantly conjugated with glycine; in contrast, both the fetal and newborn rabbits had a significant amount of taurine conjugates, and they did not have the band corresponding to glycodeoxycholic acid. Samples from the fetal and newborn rabbits contained essentially the same three bile acids, deoxycholic (DCA), chenodeoxycholic (CDCA), and cholic acid (CA), but in different proportion. CA comprised 44.6% of the total content of bile acids in the fetal rabbit gallbladder fraction and 63.5% in the intestinal fraction (compared to 80.2% and 76.5%, resp., in these fractions from newborn rabbits). The fetus samples contained a significant amount of CDCA, 31.7%, compared to 12.3% in newborn rabbits. In the newborn rabbits, 64.4% of the bile acids were located in the intestine, but in the fetuses, 60.9% of the total bile acids were associated with the gallbladder.

7397 EFFECT OF LIPOPROTEIN-X ON HEPATIC CHOLESTEROL SYNTHESIS. (Eng.) Liersch, M.; Baggio, G.; Heuck, C. C.; Seidel, D. (Medical Univ. Hosp., Univ. Heidelberg, Bergheimerstrasse 58, D-6900 Heidelberg, W. Germany). *Atherosclerosis* 26(4):505-514; 1977.

To determine the mechanism of hypercholesterolemia following bile duct obstruction, male Sprague-Dawley rats underwent i.v. infusions of lipoproteins X and B (LP-X and LP-B) isolated from the serum of patients with extrahepatic biliary obstruction and from the serum of bile duct-ligated rats. Infusion lasted for 16 hr, and each rat received 24 mg cholesterol/100 g body weight. The livers of the animals were perfused, and hepatic cholesterol synthesis was subsequently studied *in vitro*. After LP-B infusion, cholesterol synthesis (μatom ^{3}H/hr/g dry weight) was reduced to about half of its control value (7.6 ± 2, compared to 17.9 ± 1.6 in controls), but infusion with LP-X resulted in an insignificant reduction to 82% of control values. These results were confirmed with bile fistula rats, whose cholesterol synthesis is enhanced following the diversion of bile salts. After 48 hr of diversion, cholesterol synthesis increased twofold (31 ± 4, compared to 17.9 ± 1.6 in controls); LP-B infusion was followed by a significant inhibition of cholesterol synthesis (14 ± 1.7); LP-X infusion reduced cholesterol synthesis slightly (24.1 ± 3.6), but not to normal values. Analysis of the cholesterol content of the liver revealed a significant rise of hepatic free cholesterol following LP-X infusion (8.5 ± 1.1, compared to 6.3 ± 1.1 in controls and 6.6 ± 1.3 after LP-B infusion).

7398 EFFECT OF UNSATURATED LIPIDS ON THE BILE FLOW AND BILIARY EXCRETION OF CHOLESTEROL AND BILE SALTS IN RATS. (Eng.) Paul, R.; Ganguly, J. (Indian Inst. Science, Bangalore-560012, India). *Chem. Phys. Lipids* 17(2/3):315-323; 1976.

The effect of feeding safflower oil or coconut oil and the effect of phospholipid EPL (soyalecithin containing 70% linoleic acid) or egg phospholipid administration on serum, liver, and bile cholesterol and biliary flow were studied in male albino rats. Food intake of rats on a basal diet was measured, and the oils were administered by stomach tube twice daily so that total oil intake was 10% of diet. The phospholipids were administered in a similar fashion, except daily intake was 500 mg of phospholipid. After 30 days on the oil diet and 7 days on the phospholipid diet, the rats were given 4-^{14}C-cholesterol (0.25 μCi, p.o.), and the radioactivity of serum cholesterol, liver, and bile was measured. In addition, fatty acids and phospholipids of liver and bile and bile salts were determined. In rats fed the relatively less saturated safflower oil, there was an increase in the linoleic acid content of the liver cholesterol esters and triglycerides, as well as an increase in biliary phospholipids, usually at the expense of the oleic and palmitic contents of these esters. The rate of bile flow and the concentration of cholesterol in the bile were markedly higher in rats receiving the more unsaturated lipids. It is concluded that feeding lipids with a higher polyunsaturated fatty acid content causes an increase in the unsaturation of the biliary phospholipids, which, in turn, causes increased excretion of cholesterol via the bile.

7399 INCREASED SULFATION AND DECREASED 7α-HYDROXYLATION OF DEOXYCHOLIC ACID IN ETHINYL ESTRADIOL-INDUCED CHOLESTASIS IN RATS. (Eng.) Jensen, R. T.; Davis, R. A.; Kern, F., Jr. (Univ. Colorado Sch. Medicine, Denver, CO 80220). *Gastroenterology* 73(2):314-320; 1977.

To determine whether intolerance to deoxycholic acid is involved in ethinyl estradiol-associated cholestasis, deoxycholic acid conjugation, transport capacity, and metabolism were compared in control and ethinyl estradiol-treated rats. Control rats had a lower capacity to transport deoxycholic acid than taurodeoxycholic acid ($p < 0.001$) and both were decreased by ethinyl estradiol treatment (by 31% and 49%, resp.). During [24-^{14}C]sodium deoxycholate infusion, [^{14}C]biliary bile acid secretion increased, but bile flow did not change significantly in either control or ethinyl estradiol-treated rats. Ethinyl estradiol-treated animals excreted significantly less ^{14}C as taurocholic acid than did control animals (ethinyl estradiol, 23.3 ± 1.7 versus control, 29.1 ± 1.9, $p < 0.05$), consistent with an impairment of 7α-hydroxylation of taurodeoxycholic acid. Ethinyl estradiol treatment did not impair conjugation of deoxycholic acid, but did result in an increase in sulfation of taurodeoxycholic acid from 1.5% in controls to nearly 4.0% ($p < 0.01$). These results are consistent with the hypothesis that the rat has a poorer tolerance for deoxycholic acid than do certain other species. Furthermore, the rat converts deoxycholic acid, a poor choleretic, to taurocholic acid, a good choleretic. When this conversion is impaired with ethinyl estradiol treatment, sulfation may be an important alternate pathway for excretion of this potentially harmful bile acid.

7400 THE EFFECT OF BILE SALTS ON THE FORMATION AND HYDROLYSIS OF CHOLESTEROL ESTERS BY RAT LIVER ENZYMES. (Eng.) Neelon, V. J.; Lack, L. (Dept. Physiology, Univ. North Carolina at Chapel Hill, Chapel Hill, NC 27514). *Biochim. Biophys. Acta* 487:137-144; 1977.

Rat liver homogenates or rat liver microsomes containing ^{14}C-labeled cholesterol were incubated with varying amounts of different bile salts to determine the effects of bile salts on the formation and hydrolysis of cholesterol esters. Bile salts inhibited the formation of cholesterol esters in liver homogenates or liver microsomes, with chenodeoxycholate, glycochenodeoxycholate, and taurochenodeoxycholate being more potent inhibitors than their comparable cholate analogues. For example, 0.5 μmol/ml of the dihydroxy bile salt sodium taurochenodeoxycholate inhibited esterification in liver homogenates by nearly 90%, while the trihydroxy compound sodium taurocholate resulted in less than 50% inhibition at the same concentration. Microsomes prepared in potassium phosphate buffer showed similar properties with respect to esterification as did liver homogenates. Hydrolysis of cholesterol esters in liver homogenates was stimulated by bile salt addition, e.g., a 60% increase over controls was observed with 0.25 μmol/ml of taurochenodeoxycholate, while at 0.5 μmol/ml the hydrolysis was 90% greater than control values. The trihydroxylated bile salt taurocholate also stimulated the hydrolysis of cholesterol oleate in liver homogenates, but to a lesser extent (73% at 0.5 μmol/ml). Bile salts inhibited hydrolysis in microsomal preparations under conditions identical to those required for inhibition of esterification. In the presence of 100 μmol/ml potassium phosphate buffer at either pH 7.4 or 6.1, the addition of 0.5 μmol/ml of taurochenodeoxycholate inhibited hydrolysis by over 70%. This inhibitory effect was also produced by substituting potassium chloride or sodium chloride for potassium phosphate. In contrast, the presence of taurochenodeoxycholate in the absence of potassium phosphate buffer resulted in a threefold stimulation of hydrolysis. These results suggest that bile salts can significantly alter the cholesterol-cholesterol ester profile in the liver and that these effects may be influenced by small changes in the intracellular environment in the region where these reactions occur.

7401 TOXICITY OF CHENODEOXYCHOLIC ACID IN THE LIVER, GASTROINTESTINAL TRACT, KIDNEY, AND ADRENAL GLANDS OF THE RAT. (Ger.) Leuschner, U.; Schneider, M.; Loos, R.; Kurtz, W. (Zentrum der Inneren Medizin, Johann-Wolfgang-Goethe-Universitat, Theodor-Stern-Kai 7, D-6000 Frankfurt am Main, W. Germany). *Res. Exp. Med.* 171(1):41-55; 1977.

The liver, gastrointestinal tract, kidneys, and adrenal glands of 80 female Wistar rats treated with chenodeoxycholic acid (CDCA) were examined by light and electron microscopy. CDCA was administered by an endopharyngeal tube over a period of up to 60 days in daily doses of 150, 250, 500, and 1,000 mg/kg (groups 1, 2, 3, and 4, resp.). Animals were sacrificed on days 5, 15, 30, 60, and 74. All group 1-3 animals survived, but all group 4 animals died within the first 30 days. Diarrhea was not seen. The first changes in the liver (round-cell infiltration of the periportal areas, marked nuclear polymorphism, giant nuclei formation, and connective tissue proliferation) were seen after 60 days in group 1 but after only 5 days in the other groups. The morphological differences among the four groups were quantitative, not qualitative. A slight necrosis was seen in groups 2-4. By day 74, the morphological changes had regressed almost completely in group 1, and partial regression was found in groups 2 and 3. Suspect pathological changes in the gastrointestinal tract (sparse round-cell infiltration of the gastric mucosa and, occasionally, jejunal and ileal mucosa) were seen in groups 3 and 4 only. Dilated renal tubuli filled with protein cylinders were found after 5 days in 39/40 animals in groups 3 + 4. No changes were seen in groups 1 and 2. The cortex and medulla of the adrenal glands were not altered in any group. The occurrence of morphological changes in the liver, even at low doses of CDCA and in spite of potent detoxication mechanisms, suggests the existence of toxic metabolites of CDCA.

7402 ENZYMATIC DIFFERENTIATION OF HUMAN LIVER: COMPARISON WITH THE RAT MODEL. (Eng.) Greengard, O. (Harvard Medical Sch., Boston, MA). *Pediatr. Res.* 11(5):669-670; 1977.

An attempt was made to provide comprehensive data on the overall pattern of hepatic biochemical differentiation. The results of determinations of the concentration of 15 randomly selected enzymes in normal and fetal liver were collated with comparable literature data on 15 additional enzymes. The findings suggest that the quantitative pattern of enzymes in the second trimester fetal liver is significantly different from that of adult liver. Based on a specially devised activity quotient (measured as U/g immature liver over U/g adult liver), it was found that in the developing human liver, the concentrations of the various enzymes tend to change in the same direction as they do in rat liver.

7403 ENZYME ACTIVITIES OF CELLS OF DIFFERENT TYPES ISOLATED FROM LIVERS OF NORMAL AND CHOLESTATIC RATS. (Eng.) Wootton, A. M.; Neale, G.; Moss, D. W. (Royal Postgraduate Medical Sch., DuCane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 52(6):585-590; 1977.

The distribution of three membrane-bound enzymes, alkaline phosphatase, 5'-nucleotidase, and γ-glutamyl transferase, was examined in rat liver; livers were fractionated into parenchymal cells, a Kupffer cell fraction, and a biliary tract fraction by perfusion with collagenase solution. In control rat livers, the highest enzyme concentrations were found in Kupffer cell preparations. The fraction enriched with biliary tract cells showed concentrations two to four times higher than those in isolated parenchymal cells. At 24 hr after bile duct ligation there was a fourfold increase in alkaline phosphatase activity in parenchymal cells and a 2.5-fold increase of enzyme activity in the biliary tract fraction. The concentration of alkaline phosphatase in Kupffer cells remained unchanged. 5'-Nucleotidase and γ-glutamyl transferase concentrations tended to decrease after bile duct ligation for 24 hr, the most marked changes being found in Kupffer cells. After bile duct ligation for 7 days, the overall activities of hepatic alkaline phosphatase and γ-glutamyl transferase increased fourfold, and there was a small rise in 5'-nucleotidase activity. For alkaline phosphatase and γ-glutamyl transferase, the changes were found primarily in parenchymal cells and in the biliary tract fraction. There was a small rise in the activity of 5'-nucleotidase in parenchymal cells and a fall in activity in Kupffer cells. These data show marked differences in the distribution and behavior of three enzymes that are often used as alternatives in the assessment of patients with liver disease.

7404 ENZYME ACTIVITIES IN HUMAN LIVER BIOPSIES: ASSAY METHODS AND ACTIVITIES OF SOME LYSOSOMAL AND MEMBRANE-BOUND ENZYMES IN CONTROL TISSUE AND SERUM.

(Eng.) Seymour, C. A.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 52(3):229-239; 1977.

Micromethods for assaying 14 enzymes in small samples of human liver (approximately 10 mg) obtained by percutaneous needle biopsy are described, and enzyme activities for normal liver tissue and serum are reported. The plasma membrane enzymes 5'-nucleotidase and alkaline phosphatase were assayed with the use of adenosine monophosphate and 4-methylumbelliferyl (4-MeUm) phosphate, resp., as substrates. The microsomal enzymes neutral α-glucosidase and leucyl-2-naphthylamidase were assayed using 4-MeUm α-D-glucopyranoside and L-leucyl-2-naphthylamide, resp., as substrates. The biliary canalicular enzyme γ-glutamyltransferase was assayed using γ-glutamyl-2-naphthylamide as substrate. The nine acid hydrolases, acid phosphatase, phosphodiesterase, β-glucosidase, α-glucosidase, α-galactosidase, β-galactosidase, α-mannosidase, *N*-acetyl-β-glucosaminidase, and β-glucuronidase, were assayed using 4-MeUm phosphate, 4-MeUm pyrophosphate diester, 4-MeUm β-D-glucopyranoside, 4-MeUm α-D-glucopyranoside, 4-MeUm α-D-galactopyranoside, 4-MeUm β-D-galactopyranoside, 4-MeUm α-D-mannopyranoside, 4-MeUm 2-acetamide-2-deoxy-β-D-glucopyranoside, and 4-MeUm β-D-glucuronide trihydrate, resp., as substrates. Comparison of enzyme activities in normal liver tissue and control serum, resp., were: 5'-nucleotidase--liver 1.28 ± 0.17 mU/mg protein, serum 12.40 ± 0.62 mU/ml; alkaline phosphatase--liver 1.35 ± 0.17 mU/mg protein, serum 12.08 ± 0.95 mU/ml; α-glucosidase--liver 13.7 ± 2.4 mU/mg protein, serum 5.56 ± 0.76 mU/ml; leucyl-2-naphthylamidase--liver 5.08 ± 0.81 mU/mg protein, serum 1.21 ± 0.09 mU/ml; α-glutamyltransferase--liver 0.60 ± 0.06 mU/mg protein, serum 0.061 ± 0.008 mU/ml; acid phosphatase--liver 10.9 ± 0.91 mU/mg protein, serum 19.9 ± 0.7 mU/ml; phosphodiesterase--liver 0.390 ± 0.08 mU/mg protein, serum 0.024 ± 0.007 mU/ml; β-glucosidase--liver 0.840 ± 0.018 mU/mg protein, serum 0.008 ± 0.001 mU/ml; α-glucosidase--liver 0.310 ± 0.02 mU/mg protein, serum 0.029 ± 0.004 mU/ml; α-galactosidase--liver 0.060 ± 0.01 mU/mg protein, serum 0.010 ± 0.001 mU/ml; β-galactosidase--liver 0.420 ± 0.10 mU/mg protein, serum 0.073 ± 0.02 mU/ml; α-mannosidase--liver 0.250 ± 0.02 mU/mg protein, serum 0.096 ± 0.006 mU/ml; *N*-acetyl-β-glucosaminidase--liver 2.03 ± 0.28 mU/mg protein, serum 1.06 ± 0.06 mU/ml; and β-glucuronidase--liver 4.84 ± 0.43 mU/mg protein, serum 0.613 ± 0.11 mU/ml.

7405 COENZYME-INDUCED CONFORMATIONAL CHANGES AND SUBUNIT INTERACTIONS OF LIVER ALCOHOL DEHYDROGENASE.

(Eng.) Branden, C. I. (Dept. Chemistry, Agricultural Coll. Sweden, S-750 07 Uppsala, Sweden). *Biochem. Soc. Trans.* 5(3):612-615; 1977.

Coenzyme (NAD^+)-induced conformational changes and subunit interactions of liver alcohol dehydrogenase were studied. To investigate the possible importance of the hydrogen bond between the carbonyl oxygen atom of the carboxamide group and the side chain of threonine-178 for the proper positioning of the nicotinamide moiety of the coenzyme, the binding of coenzyme analogues was studied. The NAD^+ analogues either had the carboxamide group removed (leaving pyridine-adenine dinucleotide) or were substituted with an iodine atom (creating 3-iodopyridine-adenine dinucleotide). Both analogues bind in the same conformation and do not induce the isomerization reaction of the enzyme. The binding of the adenosine moiety is very similar to that of ADP-ribose or NAD^+ bound to the enzyme. The pyridine ring is not situated in the active-site pocket as is the nicotinamide ring in bound NAD^+, but lies at the surface of the crevice between the two domains of the subunit, approximately 0.15 nm away from the catalytically active zinc atom. This conformational difference is mainly accomplished by a difference in the orientation and position of the pyrophosphate group so that the sugar-phosphate chain obtains a completely different direction with respect to the enzyme in these complexes. The hydrogen bond between threonine-178 and the carboxamide group is thus an essential factor for the proper positioning of the nicotinamide moiety of NAD^+ with respect to liver alcohol dehydrogenase.

7406 MICROSOMAL HEXOSE-6-PHOSPHATE DEHYDROGENASE IN INJURED LIVER.

(Eng.) Watanabe, A. (Okayama Univ. Medical Sch., 2-5-1 Shikata-cho, Okayama, Japan). *Enzyme* 22(5):322-329; 1977.

The level of rat liver microsomal hexose-6-phosphate dehydrogenase (H6PD) during carbon tetrachloride- and thioacetamide-induced liver injury and under various pathological and physiological conditions was measured. Kinetic, immunologic, and electrophoretic studies clearly differentiated H6PD in rat liver microsomes from glucose-6-phosphate dehydrogenase (G6PD) localized in liver supernatants. H6PD activity decreased markedly 1-2 days following the administration of CCl_4 (0.5 ml/100 g by intubation) or thioacetamide (0.26 mmol/100 g, i.p.) to male Sprague-Dawley rats from a control value of 3.8 ± 0.5 mU/mg microsomal protein (well-fed rats) to 0.9 ± 0.7 ($p<0.05$) and 1.7 ± 1.2 at 24 and 48 hr, resp., after CCl_4 treatment and to 2.4 ± 1.0 at 48 hr after thioacetamide treatment. After similar treatments, G6PD activity increased significantly ($p<0.05$) from a control value of 35.1 ± 2.3 mU/mg of supernatant protein to corresponding values of 76.3 ± 13.4, 103.4 ± 20.6, and 91.4 ± 10.9. In partially hepatectomized rats or in rats receiving a glucose-casein feeding for 3 days after a 2-day starvation, G6PD activity increased significantly ($p<0.05$) to values of 49.8 ± 3.4 and 413.4 ± 52.4 mU/mg, resp., but H6PD activities were relatively unchanged at this level of significance. The decreased H6PD activities observed during liver damage may be due to the repression of H6PD synthesis but not to release of the enzyme from the damage microsome, since increases in H6PD activity were not detected in liver supernatants from CCl_4-injured liver. Decreased levels of microsomal enzymes might be primarily responsible for the impairment of drug-metabolizing capacities in injured livers.

7407 BILE 5'-NUCLEOTIDASE IN THE SERUM OF JAUNDICED RATS.

(Eng.) Mullock, B. M.; Issa, F. S.; Hinton, R. H. (Wolfson Bioanalytical Centre, Univ. Surrey, Guildford, Surrey GU2 5XH, England). *Clin. Chim. Acta* 79(1):129-140; 1977.

Serum enzymes were measured in male hooded rats (Univ. Surrey strain) made cholestatic by common bile duct ligation. Three days after ligation, serum 5'-nucleotidase, L-leucyl-β-naphthylamidase, and β-glycerophosphatase activities increased and alkaline *p*-nitrophenylphosphatase and alkaline phosphodiesterase remained unchanged or decreased. The relationship of these five enzymes to enzymes in the liver plasma membrane was investigated by affinity chromatography of the serum with an immobilized antiserum raised against highly purified liver plasma membrane. In the serum of normal rats, only L-leucyl-β-naphthylamidase was related to liver plasma membrane. In the serum of cholestatic rats, much of the 5'-nucleotidase activity and probably small proportions of alkaline *p*-nitrophenylphosphatase and phosphodiesterase were related to the corresponding enzymes in liver plasma membrane. The 5'-nucleotidase of bile was almost entirely of the liver plasma membrane type. It is concluded that changes in the serum level of this enzyme after bile duct ligation are due to leakage of bile into the blood. Another explanation for the increased levels would be the presence of fragments of plasma membrane in the sera; however, no fragments could be detected in the rat sera at the time of enzyme measurement.

7408 REDUCED INACTIVATION OF TYROSINE AMINOTRANSFERASE IN THE PERFUSED RAT LIVER IN THE PRESENCE OF ETHANOL.

(Eng.) Morland, J. (Inst. Medical Biology, Univ. Tromso, N-9000 Tromso, Norway). *Acta Pharmacol. Toxicol.* 40(1):106-114; 1977.

The effect of 0.2% ethanol on the activity of tyrosine aminotransferase was investigated in the perfused rat liver in the presence and absence of dexamethasone (final concentration 20 μg/ml) and/or cycloheximide (final concentration 25 μg/ml). Ethanol increased tyrosine aminotransferase activity both in the presence and absence of dexamethasone. The addition of ethanol or its main metabolite acetaldehyde to the enzyme assay mixture did not increase enzyme activity. Ethanol also failed to reduce the leakage of enzyme from liver to perfusate or bile. Tyrosine aminotransferase activity declined more slowly in ethanol-treated livers than in control livers when protein synthesis was inhibited by cycloheximide. Ethanol did not influence either the activity of tryptophan oxygenase or the radioactivity remaining in labeled proteins 1.5 hr after the administration of cycloheximide. It is concluded that ethanol increases tyrosine aminotransferase activity in perfused livers by specific inhibition of enzyme inactivation.

7409 DOES CHRONIC ALCOHOL CONSUMPTION REALLY INDUCE HEPATIC MICROSOMAL GAMMA-GLUTAMYLTRANSFERASE ACTIVITY?

(Eng.) Morland, J.; Huseby, N. E.; Sjoblom, M.; Stromme, J. H. (Inst. Medical Biology, Univ. Tromso, N-9001 Tromso, Norway). *Biochem. Biophys. Res. Commun.* 77(3):1060-1066; 1977.

The effect of chronic alcohol consumption on hepatic microsomal γ-glutamyltransferase (GT) activity was investigated. When male Wistar rats were fed ethanol (mean daily intake 12.5-14.2 g/kg, or 35% of caloric intake) for 6-7 weeks, they showed elevated liver and plasma GT activities (0.888 ± 0.160 U/g liver and 5.83 ± 0.35 U/l, resp.) compared with enzyme activities in control animals fed carbohydrates isocalorically (0.137 ± 0.010 U/g liver, $p<0.016$, and 4.37 ± 0.41 U/l, $p<0.047$, resp.). Similar differences in hepatic GT activity were observed after these diets were fed to rats for 1 or 4 weeks. The difference in GT activities between ethanol-fed and control rats was due to a fall in the GT activity of the latter (35-50% of zero-time value); in ethanol-treated rats, GT activity remained close to the initial pre-experimental values. Since neither ethanol nor carbohydrate feeding influenced the subcellular distribution of hepatic GT activity, no evidence for ethanol-induced microsomal GT activity was obtained. The results raise the question whether pair feeding with ethanol against carbohydrates is a proper model when the effect of ethanol on enzyme activities is to be studied.

7410 HEPATIC ALCOHOL OXIDATION AND ITS METABOLIC LIABILITY.

(Eng.) Thurman, R. G. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *Fed. Proc.* 36(5):1640-1646; 1977.

The pathways responsible for ethanol oxidation and the toxic results of its metabolism are reviewed. The predominant pathway for ethanol oxidation at low ethanol concentrations involves alcohol dehydrogenase. However, at high alcohol concentrations, up to 50% of ethanol uptake is 4-methylpyrazole-insensitive. Oxidation of ethanol under these conditions is associated with a change in the steady-state concentration of catalase-H_2O_2. Based on recent evidence, it is concluded that it is unnecessary to postulate that ethanol is oxidized directly via cytochrome P-450. Acetaldehyde production from ethanol via the microsomal subfraction can be accounted for by the combined activities of catalase-H_2O_2 and alcohol dehydrogenase. The metabolism of ethanol via alcohol dehydrogenase produces a marked reduction in the hepatocellular NAD-NADH systems. This reduction is indirectly responsible for the inhibition of glycolysis, gluconeogenesis, citric acid cycle activity, and fatty acid oxidation and may be related to some of the pathological effects observed following chronic alcohol consumption. Attempts to inhibit alcohol dehydrogenase with alkylpyrazoles and activate catalase with substrates for peroxisomal H_2O_2-generating flavoproteins, while successful, have limited applicability because of the native toxicity of the substrates themselves. Fructose and chronic pretreatment with ethanol both enhance the rate of hepatic ethanol metabolism via a similar mechanism: stimulation of mitochondrial NADH oxidation to provide NAD^+ for the alcohol dehydrogenase reaction.

7411 SOME BIOCHEMICAL ASPECTS OF CHRONIC ALCOHOL INTOXICATION. (Eng.) Pokrovsky, A. (Nutrition Inst., USSR Acad. Medical Sciences, Ustinsky pr. 2/14, Moscow C 240, USSR). *Nutr. Metab.* 21(1/2/3):194-196; 1977.

Pathways of ethanol transformation and their respective metabolic disorders in the cell are discussed. Acetaldehyde plays a role in the toxic effect of ethanol. Acetaldehyde has a significant effect on the metabolism of biogenic amines in brain tissue. Chronic alcohol intoxication at a certain stage is associated with a considerable reduction in the ratio of alcohol dehydrogenase:acetaldehyde dehydrogenase activities; this ratio determines the severity of clinical signs in intoxication. The inhibition of acetaldehyde dehydrogenase activity is the enzymological basis of hallucinations and delirium tremens. Good nutrition plays an important role in protecting against ethanol toxicity.

7412 EFFECTS OF NICOTINIC ACID ON INDUCTION OF HEPATIC DRUG METABOLIZING ENZYMES BY CHRONIC ETHANOL ADMINISTRATION. (Eng.) Tuma, D. J.; Sorrell, M. F.; Vanderhoof, J. A.; Barak, A. J. (Veterans Admin. Hosp., 4101 Woolworth Ave., Omaha, NB 68105). *Proc. Soc. Exp. Biol. Med.* 155(1):67-70; 1977.

The content of cytochrome P-450 and the activities of aniline hydroxylase and glucose-6-phosphatase were determined in the livers of Sprague-Dawley rats fed ethanol and nicotinic acid (0.5 mg/ml) singly and in combination for 4 weeks. Similar determinations were conducted in livers from rats administered 0.1% phenobarbital and nicotinic acid (150 mg/kg/day) in the drinking water alone and in combination for 4 weeks. Both chronic ethanol feeding and phenobarbital administration increased the content of cytochrome P-450 and the aniline hydroxylase activity. Glucose-6-phosphatase activity was elevated by ethanol feeding but not by phenobarbital. Nicotinic acid treatment increased the content of cytochrome P-450 and aniline hydroxylation in the ethanol-treated but not in the control or phenobarbital-treated animals. Nicotinic acid did not influence the activity of glucose-6-phosphatase in either the ethanol- or phenobarbital-treated rats. The results are consistent with the existence of a unique cytochrome P-450 that is induced by ethanol feeding, and the induction of this hemoprotein is further enhanced by the concomitant administration of nicotinic acid with ethanol.

7413 EFFECTS OF A SINGLE INGESTION OF SODIUM TAUROCHOLATE ON ESTERIFIED CHOLESTEROL CONCENTRATION IN LIVER AND CHOLESTEROL TURNOVER IN THE RAT. (Eng.) Mathe, D.; Chevallier, F. (Laboratoire de Physiologie de la Nutrition, Universite Paris-Sud, Batiment 447 F 91405 Orsay Cedex, France). *Lipids* 12(8):676-681; 1977.

To test the hypothesis that exogenous taurocholate stimulates the accumulation of hepatic esterified cholesterol and that this accumulation secondarily influences bile acid production, the overall response of cholesterol metabolism to a single ingestion of taurocholate (80 mg) was studied in rats, using the isotopic equilibrium method. The bile acid production, measured by the daily $^{14}CO_2$ output of [26-^{14}C]-cholesterol, initially decreased and then increased. Conversely, the hepatic concentration of esterified cholesterol first increased and then decreased. Moreover, the administration of 80 mg taurocholate to increase the intestinal absorption coefficient of dietary cholesterol decreased the fecal excretion and the intestinal biosynthesis of cholesterol, resulting in an excess cholesterol inflow. The classical hypothesis of negative feedback regulation of bile acid production fails to explain the observed biphasic effect of taurocholate. When the origin of taurocholate is exogenous, it appears to stimulate the storage of esterified cholesterol in the liver at the expense of bile acid synthesis. The accumulation includes not only the decrease in cholesterol transformation into bile acids but also the excess inflow of cholesterol. As exogenous taurocholate was eliminated from the body, cholesteryl ester hydrolysis occurred and provided a supplementary source of free cholesterol for bile acid synthesis.

7414 BARBITURATE-INDUCED CHOLERESIS: POSSIBLE INDEPENDENCE FROM MICROSOMAL ENZYME INDUCTION. (Eng.) Capron, J. P.; Dumont, M.; Feldmann, G.; Erlinger, S. (Hopital Beaujon, Clichy, France). *Digestion* 15(6):556-565; 1977.

The influence of four barbiturates (phenobarbital, barbital, thiopental, and pentobarbital) on bile secretion and on the hepatic microsomal system was studied in anesthetized rats to clarify the relationship between the increase in bile flow and the microsomal enzyme induction produced by barbiturates. The barbiturates were injected i.p. (8-14 mg/day/ 100 g body weight) for 4 days and the animals were studied on the 5th day. Phenobarbital, barbital, and thiopental significantly increased ($p<0.001$, $p<0.02$, and $p<0.01$, resp.) liver weight, increased cytochrome P-450 concentration in the liver ($p<0.001$), decreased pentabarbital sleeping time ($p<0.001$, $p<0.001$, $p<0.01$ resp.), and induced a hypertrophy of the smooth endoplasmic reticulum in the hepatocytes as visualized by electron microscopy. All four barbiturates significantly increased bile flow. The increase in bile flow was significantly higher in the thiopental-treated rats (+83.7%) than in rats treated with phenobarbital (+20.8%, $p<0.001$), barbital (+27.3%, $p<0.01$) or pentobarbital (+27.1%, $p<0.001$). The bile acid excretion in bile was significantly higher in the thiopental-treated rats than in the controls ($p<0.01$). There was no correlation between the increase in bile flow and the cytochrome P-450 concentration in the liver. It is concluded that the increase in bile flow observed after barbiturate treatment in the rat is possibly independent of the hepatic microsomal enzyme induction produced by these drugs.

7415 BIOCHEMICAL STUDIES OF ISOLATED RAT HEPATOCYTES FROM NORMAL AND PHENOBARBITAL-TREATED LIVER AS OBTAINED BY RATE ZONAL CENTRIFUGATION. (Eng.) Weigand, K.; Richter, E.; Esperer, H. D. (Massachusetts General Hosp., Boston, MA 02114). *Acta Hepatogastroenterol.* 24(3):170-174; 1977.

To determine whether density centrifugation could be used for the separation of centrilobular from perilobular hepatocytes, cell suspensions from normal and phenobarbital-treated rat livers were analyzed by rate zonal centrifugation in ficoll gradients. No difference in the microsomal cytochrome P-450 and NADPH-cytochrome C reductase content or in the incorporation rate of radioactive leucine was noted between light and heavy hepatocytes. After centrifugation of a mixture of radioactive phenobarbital-treated cells and normal liver cells, the specific radioactivity was constant, indicating that the hepatocytes from drug-treated liver had the same density as did the normal hepatocytes.

7416 COMPARATIVE STUDIES ON THE BINDING OF CYTOPLASMIC ^{3}H-DEXAMETHASONE-RECEPTOR COMPLEX BY NUCLEI FROM THE LIVERS OF ADULT, NEWBORN, AND FETAL RATS. (Eng.) Murakami, N.; Ichii, S. (Tottori Univ. Sch. Medicine, Yonago, Tottori 683, Japan). *J. Biochem.* 81(4):885-889; 1977.

To gain insight into the mechanism of age-related changes in tissue responsiveness to glucocorticoids, the binding patterns of dexamethasone (Dex) to cytoplasmic receptor and of cytoplasmic Dex-receptor complex to nuclei were compared in the livers of adult, 7-day-old, newborn, and fetal Wistar rats. Only one binding component with high binding affinity was observed in the cytosol from the fetal liver, while at least two binders that showed high and low affinity to Dex were detected in the cytosol of the adult liver. The dissociation constant (K_d) of the high-affinity binder in the cystosol of fetal liver was 3.6×10^{-9} M, while that in the adult liver was 0.1×10^{-10} M. Cytoplasmic Dex-receptor complexes from the adult and fetal liver were efficiently bound to nuclei from adult, 7-day-old, newborn, and fetal livers. The amount of complex bound to nuclei of the adult liver was largest, and the least binding was observed in nuclei of the newborn liver under the incubation conditions used (1.77 nM ^{3}H-Dex-receptor complex). A high-affinity binding of the receptor complex from the adult liver was observed in fetal nuclei ($K_d=1 \times 10^{-9}$ M), but nuclei from the other tissues showed low-affinity and nonsaturable binding. The Dex-receptor complex from the fetal liver bound to nuclei of the adult liver in a low-affinity and nonsaturable manner, while high-affinity binding ($K_d=6 \times 10^{-10}$ M) was observed in nuclei of the fetal liver. The binding of the fetal complex to nuclei of the 7-day-old and newborn livers showed a transitional binding pattern, with sites of high- and low-affinity binding coexisting. It is concluded that differences in the hepatic cytosol receptor-nuclear acceptor system may be attributable, at least in part, to age-related changes in tissue responsiveness to glucocorticoids.

7417 INHIBITION OF RAT LIVER ACETYL COENZYME A CARBOXYLASE BY LONG CHAIN ACYL COENZYME A AND FATTY ACID: MODULATION BY FATTY ACID-BINDING PROTEIN. (Eng.) Lunzer, M. A.; Manning, J. A.; Ockner, R. K. (Univ. California, Sch. Medicine, San Francisco, CA 94143). *J. Biol. Chem.* 252(15): 5483-5487; 1977.

The hypothesis that cytosolic proteins modulate the inhibition of rat liver acetyl-coenzyme A (acetyl-CoA) carboxylase by long chain acyl-CoA thioesters and fatty acids was tested. During Sephadex G-75 chromatography of rat liver 105,000 x *g* supernatant at 4 C, 59% of added $[^{14}C]$palmitoyl-CoA was hydrolyzed to $[^{14}C]$palmitic acid, reflecting thioesterase activity. However, both unhydrolyzed acyl-CoA and the free fatty acid were principally bound to the 12,000 dalton molecular weight fatty acid-binding protein (FABP) fraction. In experiments with the partially purified FABP fraction, both ligands bound to a limited number of sites and appeared to interact either competitively or through negative cooperativity. Partially purified rat liver acetyl-CoA carboxylase was inhibited 50% by 8 μM palmitoyl-CoA. FABP fraction in physiological concentrations enhanced the activity of acetyl-CoA carboxylase in the absence of added palmitoyl-CoA, and protected against palmitoyl-CoA inhibition of the enzyme. This protection was not attributable to thioesterase activity in the FABP preparation. The effect of oleate was also blocked by FABP fraction. Although albumin, whole cytosol, and other cytosolic fractions also protected against palmitoyl-CoA inhibition of acetyl-CoA carboxylase, the demonstrated preferential binding of inhibitors to the FABP fraction suggests that its protective effect may be relatively specific in the intact cell. These experiments support the concept that FABP may participate in the short-term regulation of lipogenesis by modulating the fatty acid and acyl-CoA inhibition of acetyl-CoA carboxylase activity. This mechanism appears to be analogous to the role of soluble polysaccharides in the modulation of fatty acid synthetase activity in Mycobacteria.

7418 RESPIRATORY ACTIVITIES OF HEPATOCYTES ISOLATED FROM RATS OF VARIOUS AGES. A BRIEF NOTE. (Eng.) Brouwer, A.; Van Bezooijen, C. F. A.; Knook, D. L. (Inst. Experimental Gerontology TNO, Lange Kleiweg 151, Rijswijk, Netherlands). *Mech. Ageing Dev.* 6(4):265-269; 1977.

Isolated liver parenchymal cells were used to study a possible decline in mitochondrial respiration, and an associated production of ATP in liver tissue with age. There were no age-related changes in the endogenous respiration of isolated rat hepatocytes. The ratio between the oxygen consumption of the isolated hepatocytes in the presence of an inhibitor of oxidative phosphorylation (50 μM atractyloside or 10 μg/ml oligomycin) and in the presence of an uncoupler (67 μM) was used as an estimation of the respiratory control ratio of mitochondria inside the isolated parenchymal cell. No significant age-related decline in the functional integrity of the mitochondria was detected.

7419 A COMPARISON BETWEEN THE MORPHOLOGIC CHANGES IN THE LIVERS OF HAMSTERS AND RATS AFTER GALACTOSAMINE TREATMENT AND THEIR CORRELATION WITH ALTERED SERUM TRANSAMINASE LEVELS. (Eng.) Pickering, R. W. (Roussel Lab., Kingfisher Drive, Covingham, Swindon, Wiltshire, England). *Arzneim. Forsch.* 27(II/9):1684-1687; 1977.

The morphologic changes in the livers of hamsters following i.p. galactosamine administration were compared with those in the livers of rats, and attempts to correlate these changes with alterations in serum transaminase levels were made. Galactosamine caused a dose-dependent increase in serum transaminase levels and an increase in the severity of liver damage score in rats. The type of damage seen after 1,500 mg/kg was predominantly submassive or massive necrosis. After 1,000 mg/kg, the predominant type of damage was focal necrosis, and after 500 mg/kg there was a mild acidophilic reaction in only 3 of 10 rats. In hamsters, all animals receiving 800 mg/kg galactosamine showed morphologic liver changes; these included submassive necrosis (1 animal), central necrosis (2), and focal necrosis locally in the periportal areas (7). Nine of 10 hamsters that received 400 mg/kg had a localized inflammatory response in the periportal region or a focal necrosis and inflammatory response in periportal region. A dose of 200 mg/kg caused no morphologic changes in hamsters. In rats receiving 1,500 mg/kg of galactosamine, the mean SGOT value was 1,893 ± 237 IU/l and the SGPT value was 1,163 ± 182 IU/l; the control levels were 54 ± 4 and 32 ± 2 IU/l, resp. In hamsters receiving 500 mg/kg of galactosamine, the mean SGOT and SGPT levels were 1,834 ± 722 and 1,612 ± 382 IU/l, resp. The results suggest that the type of damage seen in the livers of rats after galactosamine administration may be similar to that seen with human hepatitis, but the hamster exhibits a typical toxic hepatitis.

7420 MEASUREMENT OF THE BILIARY TREE VOLUME IN THE RAT UNDER Tm-CONDITIONS. (Eng.) Dammann, H. G. (I. Medical Clinic, Univ. Hamburg, Martinistrasse 52, D-2000 Hamburg, W. Germany). *Experientia* 33(8):1052-1054; 1977.

Biliary tree capacities were determined in Wistar rats under Tm-conditions (i.e., maximal tubular excretory capacity of the kidneys), using ^{35}S-BSP sodium, ^{35}S-BSP glutathione, and ^{14}C-taurocholate sodium as markers. The three agents (0.4 μmol/100 g) were injected i.v., and bile was collected in 20-sec periods up to 300 sec and in 30-sec periods up to 600 sec. The volume of the biliary capacity was calculated in two ways: the first method was based on the fact that the marker does not appear in bile as a flat concentration front, and the second method was based on the assumption that measurable radioactivity probably indicates the time of appearance of the injected dye in the left and right hepatic duct. The biliary tree capacities using ^{35}S-BSP glutathione, ^{14}C-taurocholate sodium, and ^{35}S-BSP sodium as test substances were calculated to be 69.7 ± 8.08 μl and 54.4 ± 5.25 μl, 73.2 ± 11.37 μl and 70.2 ± 11.78 μl, and 136.1 ± 16.82 μl and 115.1 ± 14.56 μl, resp., for the two methods and three substances. These values markedly exceed those reported previously. This difference may have been caused at least in part by a more homogenous distribution of the marker substance throughout the liver parenchyma in contrast to simple bolus injection studies.

7421 ^{125}I-TAN EXCRETION AND LIVER VISUALIZATION IN THE RAT. (Eng.) Pena, H. G.; Katz, J.; Watts, R. S. (Veterans Admin. Hosp., Albuquerque, NM). *Int. J. Nucl. Med. Biol.* 4(1):73-77; 1977.

The excretion of ^{125}I-toluene-azonapthol (TAN) was studied in the rat, and the potential use of this compound as a liver-scanning agent was evaluated. ^{125}I-TAN (20-25 μCi) was injected i.v. in eight male Holtzman rats. After 24 hr, 23% of the administered dose was present in the whole body, and after 9 days, only 5% remained. Excretion, chiefly urinary, was accomplished without the removal of the ^{125}I tag, as suggested by the small amount (2.69%) that appeared in the thyroid. Whole-body scans demonstrated the early hepatic and late intestinal and thyroid concentrations. The lung uptake was found to be 25% of the dose at 10 min.

7422 HEPATIC BINDING PROTEIN: THE PROTECTIVE ROLE OF ITS SIALIC ACID RESIDUES. (Eng.) Stockert, R. J.; Morell, A. G.; Scheinberg, I. H.

(Albert Einstein Coll. Medicine, Bronx, NY 10461). *Science* 197(4304):667-668; 1977.

The functional significance of sialyl residues of the hepatic plasma membrane glycoprotein was investigated. The progressive removal of sialyl residues from the hepatic binding protein (HBP) resulted in the complete abolition of the binding capacity of HBP for asialoorosomucoid; however, that for desialylated ovine submaxillary mucin (DOSM) was reduced by only 20%. This result suggests that the binding sites, which are the same for DOSM and asialoorosomucoid, are not the sialyl residues of HBP. The loss of binding capacity for asialoorosomucoid is probably the result of competition for the binding sites by galactosyl residues of HBP that become terminal after desialylation.

7423 AN AUTORADIOGRAPHIC STUDY OF THE ^{3}H-URIDINE AND ^{3}H-THYMIDINE INCORPORATION IN THE REGENERATING MOUSE LIVER. (Eng.) Lorup, C. (Inst. Zoophysiology, Univ. Lund, Helgonavagen 3b, S-223 62 Lund, Sweden). *Cell Tissue Kinet.* 10(5):477-485; 1977.

An autoradiographic study of the ^{3}H-uridine incorporation into RNA and DNA and ^{3}H-thymidine incorporation into DNA in the nucleus and cytoplasm of parenchymal cells was carried out in regenerating mouse liver after a pulse time of 2 hr. After a decreased uptake of ^{3}H-uridine into the parenchymal nucleus during the first 6 hr compared with the normal value, incorporation increased and was maximal at 36 hr; normal values were restored at 72 hr. The cytoplasmic labeling, after an initial small decrease, reached a maximum at 12 hr; this returned to normal 48 hr after hepatectomy. RNase-digestion of the liver sections left a small incorporation in both nucleus and cytoplasm, presumably DNA since it was removed by DNase treatment. This incorporation was maximal at 12 hr in the nucleus and at 24 hr in the cytoplasm. After RNase plus DNase treatment, somewhat <10% of the labeling persisted, presumably as incorporation into cell compounds other than nucleic acids. After ^{3}H-thymidine pulse, marked precursor uptake into DNA occurred about 24 hr after hepatectomy. This uptake was maximal at 48 hr and reached normal values at 72 hr. A small amount of incorporation of ^{3}H-thymidine into DNA was seen immediately after the operation, and this population of weakly labeled nuclei was still large 72 hr later.

7424 QUANTIFICATION OF TAURINE SYNTHESIS IN THE INTACT RAT AND CAT LIVER. (Eng.) Hardison, W. G. M.; Wood, C. A.; Proffitt, J. H. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *Proc. Soc. Exp. Biol. Med.* 155(1):55-58; 1977.

Total taurine synthesis was studied in isolated perfused rat and cat livers, and the relative importance of taurine synthesis from cystine sulfinic acid (CSA) and from inorganic sulfate was estimated. Rat livers, whether or not depleted of taurine by sodium cholate infusion, all synthesized taurine. Only three of six cat livers appeared to synthesize taurine at a low rate, and the negative mean synthesis rate was not significantly different from zero. Taurine specific activity fell substantially in all rat livers. The greater fall in rat livers infused with sodium cholate (mean decline 72%) than in livers not so infused (mean decline 40%) is probably the result of greater loss of ^{14}C-taurine as taurocholate in bile. The fall in taurine specific activity in the cat livers (mean decline 21%) suggested that taurine synthesis was occurring at a low rate, but this was not significant. The hepatic taurine synthesis rate from CSA was about twice as rapid in the rat as in the cat liver. About six times as much ^{14}C-CSA was decarboxylated, and about four times as much ^{14}C-CSA was converted to taurocholate per gram of liver in the rat as in the cat liver. These data suggest that taurine synthesis via the CSA decarboxylase pathway is more active in the rat than in the cat liver.

7425 ENHANCING EFFECTS OF PHENOBARBITONE AND BUTYLATED HYDROXYTOLUENE ON 2-ACETYLAMINOFLUORENE-INDUCED HEPATIC TUMORIGENESIS IN THE RAT. (Eng.) Peraino, C.; Fry, R. J. M.; Staffeldt, E.; Christopher, J. P. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439). *Food Cosmet. Toxicol.* 15(2):93-96; 1977.

The enhancing effects of 0.05% dietary phenobarbitone and of 0.5% dietary butylated hydroxytoluene (BHT) on hepatic tumorigenesis were compared in male Sprague-Dawley rats previously fed 0.02% 2-acetylaminofluorene in the diet for 18 days. Prolonged feeding of the BHT diet (for up to 407 days) produced a significant degree of enhancement (7% of controls had tumors, in comparison with 26% of BHT-treated rats, $p<0.001$); this enhancement, however, was both lower in magnitude and delayed in comparison with the enhancement produced by the phenobarbitone diet (62% had tumors). Daily phenobarbitone injections (83 mg/kg, i.p.) stimulated persistent liver enlargement and a transient fourfold increase in DNA synthesis over a 5-day period. Similar treatment with BHT (500 mg/kg) produced less pronounced liver enlargement after a delay of 1 day and did not stimulate DNA synthesis as did phenobarbitone. The results suggest that the dissimilar tumorigenic-enhancing abilities of BHT and phenobarbitone may result from differences in the effects of these agents on biochemical processes related to liver growth.

7426 SHORT-TERM AND PROLONGED TREATMENT WITH ORAL CONTRACEPTIVES AND LIVER FUNCTION. (Eng.) Kulcsar, A.; Kulcsar-Gergely, J. (Univ. Medical Sch., Debrecen 12, Hungary). *Arzneim. Forsch.* 27(II, 9):1694-1697; 1977.

The effects of progesterone and two synthetic progestogens, ethinodiol-diacetate and methylestrenolone, on liver functions were studied in female

Wistar rats. In acute experiments the animals were treated for the duration of one sexual cycle. All three compounds (10 mg/kg, s.c. for 4 consecutive days) prolonged the hexobarbital biotransformation time; this effect was reversible and normalized 48 hr after the end of treatment. Testosterone-induced microsomal mixed function oxidase activity remained at the level of controls after methylestrenolone pretreatment and was even higher in the ethinodiol-diacetate and progesterone-pretreated animals. Subacute and chronic treatment with the progestogens (total dose 60 mg/kg) for two or more sexual cycles resulted in the same slight inhibition of hexobarbital biotransformation. Chronic progesterone administration significantly prolonged the hexobarbital biotransformation time; this impairment was reversible. The results indicate that hexobarbital metabolism is moderately and transiently inhibited during short-term and prolonged progesterone and progestogen treatment. This effect is readily reversed by interrupting drug administration or inducing microsomal enzymes with testosterone.

7427 THE ASSOCIATION OF LYSOSOMAL ENZYMES WITH NUCLEI DURING ENZYME INDUCTION IN RAT LIVER. (Eng.)

Mak, I. T.; Wells, W. W. (Dept. Biochemistry, Michigan State Univ., East Lansing, MI 48824). *Arch. Biochem. Biophys.* 183(1):38-47; 1977.

The association of lysosomal enzymes with nuclei during enzyme induction was studied in the rat liver. Male Holtzman rats were fasted for 3 days and refed a diet high in carbohydrate (68.9%). The induction of liver glucose 6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase was monitored for up to 48 hr after refeeding. Induction occurred by 24 hr, and by 48 hr, 4.2- and 1.5-fold increases were observed for glucose 6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase, resp., compared with that of livers of pellet-fed rats. After refeeding, lysosomes increased in fragility as judged by an increased release of acid phosphatase activity during standard homogenization. Fragility was greatest 3 hr after refeeding, but normal fragility was observed 24 hr after refeeding. Nuclei isolated just before refeeding revealed small latent acid phosphatase activity (4-6%). After refeeding the carbohydrate-rich diet, a transient and significant ($p<0.01$) increase in the latent activity occurred that was maximal (20%) at 1 hr returning to normal by 24 hr. Cross-mixing the 800 x *g* nuclear pellet from livers of animals starved for 3 days with the 800 x *g* supernatant fraction from livers of animals refed the carbohydrate-containing diet did not alter the nuclear lysosomal-free (overt) or latent (detergent-released) enzyme activity. Similarly, mixing the 800 x *g* nuclear pellet from livers of animals refed for 1 hr with the 800 x *g* supernatant fraction from livers of animals starved for 3 days, but not refed, did not change the nuclear lysosomal-free or latent enzyme activity. Purified nuclei lost acid phosphatase activity, but those isolated from the livers of rats refed for 1 hr retained 10% of the enzyme latency, whereas all latency was lost from those isolated from uninduced rats. β-Galactosidase became associated with the nuclei with the same temporal pattern as for acid phosphatase. However, no variation in nuclear content of cytosolic lactate dehydrogenase occurred as a result of feeding the high-carbohydrate diet to starved rats. When similarly starved rats were refed a diet high in lipid and carbohydrate-free, no induction of glucose 6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase was observed. Lysosomes were not temporarily fragile, and purified nuclei did not exhibit increased latency of acid phosphatase activity. The results support the hypothesis that liver lysosomal enzymes participate in early signals in the induction of enzymes of lipogenesis.

7428 HEPATIC PATHWAYS OF ETHANOL AND ACETALDEHYDE METABOLISM AND THEIR ROLE IN THE PATHOGENESIS OF ALCOHOL-INDUCED LIVER INJURY. (Eng.)

Teschke, R.; Hasumura, Y.; Lieber, C. S. (2. Medizinische Universitatsklinik, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany). *Nutr. Metab.* 21(Suppl. 1): 144-147; 1977.

To assess the role of various enzymes in ethanol metabolism of intact liver tissue, rat liver slices were incubated with 50 mM ethanol, and rates of ethanol disappearance were measured by gas liquid chromatography. In addition, hepatic pathways of ethanol and acetaldehyde metabolism and their role in the pathogenesis of alcohol-induced liver injury are reviewed. Compared with control incubations, the addition of the alcohol dehydrogenase (ADH) inhibitor, pyrazole (2 mM), failed to abolish ethanol metabolism and decreased the rates of ethanol oxidation by only 50%. Pretreatment of rats with the catalase inhibitor, 3-amino-1,2,4-triazole, abolished catalase activity in the liver, but had no inhibitory effect on the rates of ethanol metabolism in liver slices in the absence or presence of 2 mM pyrazole when compared with incubations carried out with liver slices of control rats. The pyrazole-insensitive, and therefore ADH-independent, ethanol oxidation in liver slices was decreased by 10 mM butanol, which is substrate and inhibitor of the microsomal ethanol oxidizing system (MEOS). These findings indicate that ethanol metabolism in intact liver tissue can be accounted for by ADH and by the MEOS, whereas, the role of catalase appears to be insignificant. Previous experiments have shown that chronic ethanol consumption results in a decreased capacity of mitochondria to metabolize acetaldehyde. It is concluded that hepatic injury due to chronic ethanol consumption can be attributed at least in part to increased levels of acetaldehyde.

7429 METABOLISM OF ETHANOL HYDROGEN IN MAMMALS. (Eng.)

Lundquist, F.; Grunnet, N.; Damgaard, S. E.; Thieden, H. I. D. (Dept. Biochemistry, Panum Inst., Blegdamsvej 3c, DK-2200, Copenhagen N., Denmark). *Trends Biochem. Sci.* 2(8):173-175; 1977.

The fate of the two carbon-bound hydrogen atoms in the primary alcohol group in ethanol is reviewed.

The metabolism of these two hydrogens is responsible for several metabolic changes seen in the liver after the consumption of even small quantities of ethanol, namely, a reduction in the rate of carbon dioxide formation (through the inhibition of the tricarboxylic acid cycle), an increase in the ratio of reduced to oxidized forms of a number of substrate couples, and, possibly, fat accumulation. Enzyme systems involved in ethanol metabolism (alcohol dehydrogenases, catalase, and hydroxylases or mixed function oxidases), different pathways for ethanol oxidation, intracellular localization of acetaldehyde oxidation, oxidation of cystolic NADH in the respiratory chain, and transhydrogenations and compartmentation of coenzymes and substrate pools are discussed.

7430 BILE ACID EXCRETION: THE ALTERNATE PATHWAY IN THE HAMSTER. (Eng.) Galeazzi, R.; Javitt, N. B. (New York Hosp.-Cornell Medical Center, New York, NY 10021). *J. Clin. Invest.* 60(3):693-701; 1977.

Esterification and urine excretion of bile acids were measured in hamsters to evaluate the importance of this pathway as a model for the study of human liver and biliary disease. Bile acids were quantitated by gas-liquid chromatography after formation of methyl ester acetate derivatives. To study bile acid pool size, ^{14}C-24-labeled bile acids were injected into the jugular vein and following bile duct ligation, bile was removed from the gallbladder and biliary tree 24 hr later. The total serum bile acid levels, 454 μg/ml at 24 hr, dropped to 73 μg/ml by 96 hr; bilirubin rose from 64 to 133 μg/ml during this time period. The aggregate of cholic acid (61-86%) and chenodeoxycholic acid (10-31%) was found to constitute 90% or more of the total serum bile acids. Bile acid concentration in the urine fell continuously with time. The total amount excreted in the urine (4.9-12.9 mg%) probably approximates the primary bile acid pool size, with cholic acid comprising 51-71%; deoxycholate was <11% of the total pool. The percentage of ester sulfates of each bile acid was always greater in urine than in serum. The percentage of ester sulfates in bile taken from the hepatic ducts proximal to the ligature at 96 hr was elevated compared to normal bile but appreciably lower than the quantity in urine. Concomitant bilateral renal pedicle and bile duct ligation produced very high serum bile acid concentrations containing a larger proportion of sulfated bile esters than found following bile duct occlusion alone. Thioacetamide (20 mg/100 g, i.p.) administered in two injections 24 hr apart led to large amounts of serum bile acids (31 μg/ml at 24 hr, 75 μg/ml at 96 hr); a similar regimen given to bile duct-ligated hamsters produced even greater increases. After the 24-hr thioacetamide treatment, serum cholic acid was not sulfated and serum chenodeoxycholate was 10-44% esterified. The thioacetamide-treated hamsters showed no difference in the percentage of sulfation of bile acids in urine, while the total bile acids in the urine was less when compared to the bile duct-obstructed animals. Bile acid excretion as ester sulfates is quantitatively important in the hamster and can serve as a model for studies applicable to humans.

7431 BEHAVIOUR OF ^{125}I-FIBRINOGEN AND ^{131}I-ALBUMIN IN EXPERIMENTAL GALACTOSAMINE-INDUCED HEPATITIS. (Eng.) Mahn, I.; Merkel, H.; Sattler, E. L.; Muller-Berghaus, G. (Section Clinical Immunology and Blood Transfusion, Justus Liebig Univ., Giessen, Germany). *Gut* 18(7):547-555; 1977.

To differentiate between faulty liver synthesis of coagulation factors and alterations of the coagulation components caused by disseminated intravascular coagulation, the turnover of ^{125}I-fibrinogen and ^{131}I-albumin was studied in the course of galactosamine-induced hepatitis in New Zealand rabbits. All animals were injected with ^{125}I-fibrinogen (20-30 μCi) and ^{131}I-albumin (20-30 μCi) 48 hr before the start of the studies. The rabbits (10-15 per group) were treated as follows: group A epsilon-aminocaproic acid (EACA) was injected (1 g/kg, i.v.) and galactosamine (1 g/kg) was consecutively infused for 30 min followed by continuous infusion of EACA (0.5 g/kg/hr); group B received a similar series except that heparin (1,500 U/kg) was injected before the EACA injection and then was continuously infused at 750 U/kg/hr; group C was given EACA in the same dosage as groups A and B; and group D received an isotonic saline infusion (6 ml/hr). Blood samples were removed at 0, 0.5, 4, 8, 12, and 24 hr. Histologic examination of galactosamine-treated rabbits showed foci of hepatic necrosis within all lobules. In group A rabbits only, fibrin-rich microclots were observed (7/12) in kidney glomerular capillaries. The ^{125}I-radioactivity was highest in group A organs except for the lung, which was similar to the other groups. The ^{131}I-radioactivity was distributed equally in all corresponding organs, except that lungs contained twice the activity of the kidneys, liver, or spleen. Partial thromboplastin time rose while prothrombin time and factor V activity fell in groups A and B as compared to groups C and D. Platelet count in group A dropped as compared to groups C and D; heparin (group B) did not alter this decrease, but it slowed the decrease in fibrinogen concentration noted in group B rabbits as compared to those in group A. The hematocrit and ^{131}I-albumin activity decreased equally in all groups. An acceleration of the ^{125}I-fibrinogen elimination from the plasma was observed between 8 and 12 hr after the start of galactosamine infusion. The elimination of ^{131}I-albumin in plasma as well as the distribution of ^{131}I-radioactivity in organs was similar in all rabbits independent of the treatment with galactosamine, EACA, or heparin. The results indicate that, in addition to diminished synthesis of coagulation factors, disseminated intravascular coagulation is involved in galactosamine-induced hepatitis and contributes to the hemostatic disorder. Heparin treatment in severe liver disease is of dubious value.

7432 INFLUENCE OF PHENOBARBITAL ON FACTORS RESPONSIBLE FOR HEPATIC CLEARANCE OF INDO-

CYANINE GREEN IN THE RAT: RELATIVE CONTRIBUTIONS OF INDUCTION AND ALTERED LIVER BLOOD FLOW. (Eng.) McDevitt, D. G.; Nies, A. S.; Wilkinson, G. R. (Dept. Therapeutics and Pharmacology, Queens Univ., Belfast, Northern Ireland). *Biochem. Pharmacol.* 26(13):1247-1250; 1977.

The influence of phenobarbital, 3,4-benzpyrene and 3-methylcholanthrene on indocyanine green (ICG) clearance was investigated in Sprague-Dawley rats. ICG clearance following rapid i.v. administration of 1, 10, and 50 mg/kg was dose-dependent, and pretreatment for 10 days with the inducing agents produced an increase in clearance only in the case of phenobarbital. All three inducers, when given in this manner, have been reported to produce equivalent increases in ligandin; consequently, this protein cannot be a major rate-limiting factor for hepatic ICG removal in the rat. Of the three inducing agents studied, only phenobarbital increases liver blood flow. The relative contribution of this change versus any increase in the liver's intrinsic ability to remove ICG was estimated using a perfusion-limited model of hepatic elimination. Although the influence of the altered flow decreased with increasing ICG dose, the changes in both flow and intrinsic clearance were directly proportional to the increase in liver mass produced by phenobarbital. It is concluded that the influence of phenobarbital on ICG clearance in the rat is due to a larger liver with a proportionate increase in blood flow and is not a consequence of the induction of any specific uptake protein.

7433 ROLE AND MECHANISM OF PERIPHERAL FATTY ACID MOBILIZATION IN 2-MERCAPTOETHANOL-INDUCED FATTY LIVER. (Eng.) Sabourault, D; Giudicelli, Y.; Nordmann, J.; Nordmann, R. (Laboratoire de Biochimie de la Faculte de Medecine de Paris-Ouest, 47, Boulevard de l'Hopital, 75013 Paris, France). *Lipids* 12(8):641-644; 1977.

To test the hypothesis that increased peripheral fat mobilization could be involved in 2-mercaptoethanol- and 2-mercaptoacetate-induced fatty liver, the effects of these two agents on lipolytic activity in rat adipose tissue were studied. The rate of free fatty acid release was enhanced 2.1-fold by 2 mM 2-mercaptoethanol and 2.4-fold by 2 mM 2-mercaptoacetate; the rate of glycerol release was unaffected by 2-mercaptoethanol but significantly increased by 2-mercaptoacetate. These results suggest that these compounds may reduce the free fatty acid re-esterification process in adipose tissue. The ATP level in adipose tissue incubated with 2-mercaptoethanol was depressed 54%, and that in tissue incubated with 2-mercaptoacetate was depressed 60%. When pyrazole was injected prior to 2-mercaptoethanol or 2-mercaptoacetate, the rise in blood free fatty acids occurring 3 or 8 hr after the treatment was almost completely prevented by 2-mercaptoethanol, whereas it was unaffected by 2-mercaptoacetate. Pyrazole reduced or completely abolished the increase in liver triacylglycerol found 3 or 8 hr after 2-mercaptoethanol administration, whereas it failed to affect the magnitude of the 2-mercaptoacetate-induced fatty liver. Lipolysis was studied in fat pads first exposed to 1 mM pyrazole and then incubated in the presence of 2 mM 2-mercaptoethanol or 2-mercaptoacetate. Preincubation with pyrazole resulted in the suppression of the stimulating effect of 2-mercaptoethanol on free fatty acid release; preincubation with pyrazole failed to alter the effects of 2-mercaptoacetate. The results indicate that the increase in free fatty acid mobilization from adipose tissue and the fatty liver induced by 2-mercaptoethanol are due to 2-mercaptoacetate or to one of its metabolites. 2-Mercaptoethanol appears to be oxidized *in vivo* by alcohol dehydrogenase.

7434 CHRONIC COPPER POISONING IN SHEEP. III. THE DISTRIBUTION OF SOLUBLE COPPER- AND ZINC-BINDING LIVER PROTEINS OF LAMBS COMPARED WITH ADULT SHEEP. (Eng.) Soli, N. E.; Froslie, A.; Norheim, G. (Veterinary Coll. Norway, P.O. Box 8146, Dep., Oslo 1, Norway). *Acta Pharmacol. Toxicol.* 40 (5):570-574; 1977.

The distribution of copper- and zinc-binding proteins among soluble hepatic proteins was studied by gel filtration in newborn lambs of one normal ewe and one ewe with chronic copper poisoning. For the normal ewe and her lamb, the copper-binding proteins were separated into three different fractions; the mean molecular weights of these were 64,000 daltons (fraction I), 30,000-35,000 daltons (fraction II), and 8,000-10,000 daltons (fraction III). In these two animals, and in the ewe with copper poisoning, fraction I was the main fraction. In the remaining lamb, fraction III was the dominant one. This lamb had the highest liver copper concentration of all the animals, and a significantly higher amount of copper was found in fraction III, compared with that in the normal lamb. The main zinc-binding fractions in the normal ewe and her lamb corresponded well to fraction I and II with regard to the copper-binding proteins. No zinc was found in the fraction corresponding to fraction III in any of the samples, but a fraction with a molecular weight less than 1,500 daltons was present in all the samples. A high molecular weight (45,000-50,000 daltons) zinc-binding fraction was found in the normal ewe. The percentage of extractable copper for both lambs and ewes fell when the copper concentration in the liver increased. The high copper concentration in the liver of this lamb indicates that a placental transfer and accumulation of copper is possible in sheep.

7435 PORPHYRIN INDUCTION: EQUIVALENT EFFECTS OF 5αH AND 5βH STEROIDS IN CHICK EMBRYO LIVER CELLS. (Eng.) Stephens, J. K.; Fischer, P. W. F.; Marks, G. S. (Dept. Pharmacology, Queen's Univ., Kingston, Ontario, Canada). *Science* 197(4304):659-660; 1977.

The potency of 5αH and 5βH steroids in inducing δ-aminolevulinic acid (ALA) synthetase and porphyrin accumulation was investigated in chick embryo liver cells maintained in serum-free medium. The porphyrin-inducing activities of 5α-pregnane-3,20-dione and of

5α-androstane-3α-ol-17-one did not differ from those of their respective epimers at any of the doses tested (1, 3, and 10 μg/ml). The porphyrin-inducing activities of 5α-androstane-3,17-dione and of 5α-pregnane-3β-ol-20-one did not differ from those of their respective epimers, thus strengthening the conclusion that there is no difference between the porphyrin-inducing activity of 5αH and 5βH epimers. The ALA synthetase-inducing activities of 5α-pregnane-3,20-dione, 5α-pregnane-3α-ol-20-one, and 5α-androstane-3,17-dione (3, 10, and 30 μg/ml) did not differ from those of their respective epimers except in the case of the α-pregnane epimers at doses of 30 μg/ml. The β-pregnane epimers were devoid of activity at this dose because of a direct toxicity to chick embryo liver cells. The results show that there is no steric requirement for activity in steroids in the systems investigated.

7436 PHARMACOLOGY OF CHENODEOXYCHOLIC ACID. I. PHARMACEUTICAL PROPERTIES. (Eng.) van Berge-Henegouwen, G. P.; Hofmann, A. F.; Gaginella, T. S. (Nijmegen Univ. Medical Sch., Nijmegen, Netherlands). *Gastroenterology* 73(2):291-299; 1977.

Chemical and physical properties of eight different commercial preparations of chenodeoxycholic (chenic) acid were defined to provide background information for subsequent bioavailability studies. All samples had high chemical purity by gas-liquid chromatography and by enzymatic analysis, but samples differed considerably in crystal morphology when examined by scanning electron and light microscopy. Only two samples were crystalline by X-ray diffraction, and these two samples had unequivocal endotherms by differential thermal analysis. In buffer, chenic acid showed low equilibrium solubility (less than 0.1 mM) at pH 6, but solubility increased strikingly above pH 6.8. In a miscellar solution simulating intestinal content during digestion, solubility was higher than in buffer below pH 6 and then increased markedly above pH 6.2. When the rate of dissolution of chenic acid in simulated intestinal content was characterized, all of the samples, with the exception of one that was composed of large crystals by microscopy, dissolved rapidly, with most samples showing greater than 90% dissolution by 15 min. After milling, the sample that originally did not dissolve rapidly also dissolved rapidly. It is concluded that pure chenic acid, irrespective of its crystal habit, should dissolve rapidly in intestinal content provided its particle size is small.

7437 CHANGE IN BILE COMPOSITION DURING GALLSTONE FORMATION IN GERBILS. (Eng.) van der Linden, W.; Bergman, F. (Dept. Pathology I, Lasarettet, Umea, Sweden). *Z. Ernahrungswiss.* 16(2): 115-119; 1977.

Changes in bile composition were studied during experimentally induced cholesterol gallstone formation in gerbils. Thirty-eight animals received a diet containing 1% cholesterol and 0.5% cholic acid, and 28 controls received a normal diet. Bile samples were assayed for cholesterol, bile acid, and phospholipid content after 1 or 3 months on the diet. After 1 month on the lithogenic diet, the percentage of biliary cholesterol was 9.83 ± 0.74%, while that in the controls was 4.97 ± 0.36% ($p<0.01$). After 3 months on the experimental diet, gallstones began to appear in the gerbils, and the changes in their bile composition became more pronounced. The cholesterol fraction was 21.86 ± 2.52% in the experimental animals, and the bile acid fraction had decreased from 83.41 ± 2.24% at 1 month to 71.70 ± 2.52% at 3 months; the control level was 89.30 ± 0.70%. There was also a decrease in the bile acid: phospholipid ratio; the ratio was 17.10 in controls, compared with 15.77 after 1 month and 12.89 after 3 months in animals on the experimental diet. The results show that changes in bile composition on a lithogenic diet are essentially due to a change in the relationship between cholesterol and bile acids.

7438 ENZYME ACTIVITIES OF LIVER PLASMA MEMBRANE IN RAT BILE AFTER THE INTRABILIARY RETROGRADE INFUSION OF TRITON X-100. (Eng.) Nakae, H.; Shiomi, Y.; Muranishi, S. (Faculty Pharmaceutical Sciences, Kyoto Univ., Yoshida-shimoadachi-cho, Sakyo-ku, Kyoto, Japan). *Chem. Pharm. Bull.* 25(6):1447-1449; 1977.

To determine whether a part of the bile canalicular site of the liver plasma membrane is solubilized by Triton X-100 treatment, the bile protein concentration and the activities of three bile canalicular enzymes (alkaline phosphatase, 5'-nucleotidase, and adenosine triphosphatase) were determined in rat liver plasma membrane after the retrograde infusion of a 4% Triton X-100 solution. The protein concentration in bile was increased by a factor of five by the treatment, and this increased level lasted for at least 6 hr without diminution (5.3 ± 2.3 mg/ml before treatment, 24.5 ± 4.0 mg/ml 6 hr after treatment). The activities of all three enzymes were also elevated and were not decreased for 6 hr. The alkaline phosphatase activity was elevated by a factor of 8, and the activities of the other enzymes by 1.5 to 3. The results show that part of the bile canalicular site of the liver plasma membrane is solubilized by the treatment.

7439 PATHOGENESIS OF ALCOHOL-INDUCED ACCUMULATION OF PROTEIN IN THE LIVER. (Eng.) Baraona, E.; Leo, M. A.; Borowsky, S. A.; Lieber, C. S. (Bronx Veterans Admin. Hosp., Bronx, NY 10468). *J. Clin. Invest.* 60(3):546-554; 1977.

The mechanism of protein accumulation in the livers of male weanling CD rats fed diets containing 36% of calories as ethanol was studied to determine the role of increased anabolism and decreased catabolism of liver proteins. L-[^{14}C]leucine (325 mCi/mmol) was injected into the dorsal penile vein, to study the incorporation of label with time, using 0.3-, 1-, 2.5-, 5-, 7.5-, 10-, 30-, 45-, 90-, and 120-min injection intervals before sacrifice. Microtubule concentration was measured by the binding of ^{3}H-cholchicine to free tubulin. When control and ethanol-fed animals were compared, ethanol feeding lowered body weight by 9.4% ($p<0.001$), and increased liver weight (9.72 ± 0.47 g versus 8.47 ± 0.36 g, $p<0.01$), total liver lipids (145 ± 10 to 302 ± 35 mg/100 g, $p<0.01$), and total liver proteins (from 573 ± 23 to 706 ± 40 mg/100 g, $p<0.01$), whereas total liver DNA was similar in both groups of rats. Liver histology revealed hepatocytes with significantly larger areas in ethanol-fed animals than in the control animals. After correcting for recovery and plasma protein contamination, transferrin and albumin concentrations increased in total, microsomal, and cytosol liver extracts after alcohol feeding. Albumin and transferrin showed greater increases per 100 g body weight than per g liver weight due to the hepatomegaly caused by alcohol treatment. Liver ferritin decreased in concentration after ethanol ingestion (0.33 ± 0.03 versus 0.40 ± 0.02 mg/g liver, $p<0.03$). Ethanol-fed rats had a higher serum leucine concentration (235 ± 16 nmol/ml versus 133 ± 17 nmol/ml, $p<0.001$), a higher liver concentration of free leucine (273 ± 32 nmol/g versus 153 ± 15 nmol/g, $p<0.02$), and a lower specific activity of leucyl-t-RNA. Proalbumin contained over 90% of the radioactivity. The radioactive leucine content was maximal in liver proteins by 10 min, and the computed rate of total liver protein synthesis was higher in ethanol-fed rats than in controls (22.4 versus 14.5 mg/hr/100 g). The appearance of radioactivity in serum albumin was delayed, and total tubulin but not free tubulin in liver cytosol was decreased significantly in ethanol-fed rats compared to controls. The results suggest that ethanol feeding may induce changes in liver microtubules leading to protein accumulation with concomitantly elevated protein synthesis in response to lower plasma protein levels.

7440 ACTION OF MICROBIAL FLORA OF THE DIGESTIVE TRACT ON CHOLIC ACID BIOSYNTHESIS IN THE RAT.

(Fre.) Sacquet, E.; Mejean, C.; Leprince, C.; Riottot, M. (Laboratoire des Animaux sans Germes du CNRS, au CNRZ, Jouy-en-Josas, 78350, France). *Biochim. Biophys. Acta* 499(1):67-72; 1977.

The percentage of cholic acid in the feces of axenic rats and the percentage of cholic acid and bacterial metabolites in the feces of holoxenic rats were compared. Male Fisher rats were fed a semisynthetic diet (220 g casein, 580 g cornstarch, 90 g corn oil, 50 g cellulose, plus vitamins, and minerals) containing radioactively labeled 2,4-cholic acid (^{3}H-CA) and 24-chenodeoxycholic acid (^{14}C-CDA) according to three experimental protocols. (1) Four axenic rats were given 100,000 disintegrations/minute (dpm) ^{3}H-CA and 20,000 dpm ^{14}C-CDA per gram of food for 3 weeks, and feces were collected during the third week. (2) Three holoxenic rats were given 180,000 dpm ^{3}H-CA and 14,800 dpm ^{14}C-CDA per gram of food, and feces were collected 12-15 days after introduction of the acids. (3) Three holoxenic rats were given 630,000 dpm ^{3}H-CA and 20,000 dpm ^{14}C-CDA. A second group of three holoxenic rats received 311,000 dpm ^{3}H-CA and 20,000 dpm ^{14}C-CDA. A significant ($p<0.001$) difference was observed in the excretion of ^{3}H-CA by axenic and holoxenic rats (2.5 ± 0.32 and 4.3 ± 0.19 µmol/100 g body weight, resp.) and in the excretion of ^{14}C-CDA (4.9 ± 0.71 and 7.5 ± 0.33 µmol/100 g body weight, resp.). However, the total amount of 12alpha-hydroxylated bile acids expressed as percentage of total biliary acids excreted and corrected for loss of ^{3}H by bacterial metabolism was similar for axenic and holoxenic rats (33.8% and 36.4%-38.3%, resp.), demonstrating that intestinal microflora only slightly modify 12alpha-hydroxylated bile acid synthesis.

7441 TIME SEQUENCE OF CHANGES IN HEPATIC FATTY ACID SYNTHESIS IN RATS MEAL-FED POLYUNSATURATED FATTY ACIDS.

(Eng.) Clarke, S. D.; Romsos, D. R.; Leveille, G. A. (Johns Hopkins Univ., Sch. Hygiene and Public Health, 615 North Wolfe St., Baltimore, MD 21205). *J. Nutr.* 107(8):1468-1476; 1977.

Male Sprague-Dawley rats were fed daily meals containing methyl esters of palmitate ($C_{16:0}$), stearate ($C_{18:0}$), linoleate ($C_{18:3}$), and linolenate ($C_{18:2}$) to determine the influence of these fatty acids on glucokinase and fatty acid synthetase activities and on *in vivo* rates of fatty acid synthesis in the liver. The addition of 7% $C_{16:0}$ or 3% $C_{18:3}$ to a fat-free basal diet did not alter the rate at which the diet was removed from the stomach and small intestine. The consumption of eight meals containing $C_{18:2}$ significantly reduced hepatic fatty acid synthetase activity and *in vivo* rates of fatty acid synthesis by 40%, but did not alter glucokinase activity. At least three meals containing $C_{18:2}$ or $C_{18:3}$ were required to inhibit hepatic fatty acid synthesis. Conversely, after rats consumed $C_{18:2}$, more than two meals of a fat-free diet were required to increase hepatic rates of fatty acid synthesis. Dietary $C_{16:0}$ and $C_{18:0}$ did not alter the rates of hepatic fatty acid synthesis. Glucokinase was not influenced by any of the methyl esters. The results suggest that polyunsaturated fatty acids can specifically influence hepatic fatty acid synthesis and fatty acid synthetase activity without altering glucokinase activity, and that meal-fed rats must consume at least three meals containing polyunsaturated fatty acids before hepatic fatty acid synthesis or fatty acid synthetase activity is altered.

7442 EFFECT OF MATERNAL ETHANOL CONSUMPTION ON FOETAL AND NEONATAL RAT HEPATIC PROTEIN SYNTHESIS.

(Eng.) Rawat, A. K. (Alcohol Res. Center Medical Coll. Ohio, Toledo, OH 43614). *Biochem. J.* 160(3):653-661; 1976.

The effects of maternal ethanol consumption on the rates of protein synthesis were investigated in the livers of fetal and neonatal rats both *in vivo* and *in vitro*; the effects of ethanol consumption on the activities of enzymes involved in protein synthesis and degradation were also studied. The rates of general protein synthesis by ribosomes *in vitro*, studied by measuring the incorporation of [^{14}C]leucine into ribosomal protein, showed that maternal consumption of 6% (volume/volume) ethanol for 2 weeks resulted in an inhibition of the rates of protein synthesis by both fetal and neonatal livers. The rates of incorporation of i.v. injected [^{14}C]-leucine into hepatic proteins were also significantly lower in the fetal, neonatal, and adult livers from the ethanol-fed group (68 ± 6, 100 ± 8, and 76 ± 5 pmol/30 min/mg protein, resp., versus 108 ± 6, 152 ± 10, and 120 ± 10 pmol/30 min/mg, resp., in controls; $p<0.001$, $p<0.01$, and $p<0.001$, resp.). Incubation of adult rat liver slices with ethanol resulted in an inhibition of the incorporation of [^{14}C]leucine into hepatic proteins; however, this effect was not observed in the fetal liver slices. This effect of externally added ethanol was at least partially prevented by the addition of 2 mM pyrazole to the adult liver slices. Pyrazole addition to fetal liver slices was without significant effect on the rates of protein synthesis. Cross-mixing experiments showed that the capacity of both hepatic ribosomes and pH 5 enzyme fractions to synthesize proteins was decreased in the fetal liver from the ethanol-fed group. Maternal ethanol consumption resulted in a decrease in hepatic total RNA content, RNA/DNA ratio, and ribosomal protein content in the fetal liver. Fetal hepatic DNA content was not significantly affected. Ethanol consumption resulted in a significant decrease in proteolytic activity and the activity of tryptophan oxygenase in the fetal, neonatal, and adult livers. The mechanisms of inhibition of protein synthesis observed here in the fetal liver after maternal ethanol consumption may be responsible for at least some of the changes observed in "fetal alcohol syndrome."

7443 TAUROLITHOCHOLATE INHIBITS TAUROCHOLATE UPTAKE BY ISOLATED HEPATOCYTES AT LOW CONCENTRATIONS. (Eng.) Schwenk, M.; Schwarz, L. R.; Greim, H. (Gesellschaft fur Strahlen- und Umweltforschung, Munchen, Abteilung fur Toxikologie, D-8042 Neuherberg, W. Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(2):175-179; 1977.

The inhibitory effect of taurolithocholate on bile acid transport was studied in isolated rat hepatocytes. A Lineweaver-Burk plot showed that taurolithocholate inhibits taurocholate uptake by isolated liver cells noncompetitively. Inhibition was instantaneous and inversely related to the cell number in the incubation mixture. The K_i was 7 μM in the presence of 2 mg cellular protein/ml. Secretion of taurocholate by isolated liver cells was not affected by taurolithocholate up to a concentration of 50 μM. This result indicates a difference between the carrier for taurocholate uptake and the carrier for taurocholate secretion. Inhibition of bile acid uptake by liver cells may be involved in the pathogenesis of lithocholate-induced cholestasis.

7444 REGULATION OF PALMITATE METABOLISM BY CARNITINE AND GLUCAGON IN HEPATOCYTES ISOLATED FROM FASTED AND CARBOHYDRATE REFED RATS. (Eng.) Christiansen, R. Z. (Inst. Medical Biochemistry, Univ. Oslo, Oslo, Karl Johansgt. 47, Norway). *Biochim. Biophys. Acta* 488(2):249-262; 1977.

The effect of glucagon was compared with that of carnitine on the partitioning of fatty acids between oxidation and esterification in isolated liver cells from fasted and fasted-carbohydrate refed Wistar rats. Glucagon stimulated the oxidation of palmitate in the liver cells isolated from carbohydrate-refed rats and incubated in a simple salt medium. The maximal stimulation was observed at a glucagon concentration of 4×10^{-8} M and was noticeable after 5 min of incubation. The stimulation of the oxidation was balanced mainly by the inhibition of triacylglycerol synthesis. The extent of stimulation was not dependent on the concentration of intracellular carnitine, but was decreased at higher concentrations of palmitate in the medium. Glucagon had no significant effect on palmitate metabolism in the cells isolated from fasted rats. It seems probable that those cells are isolated in the activated state as far as it concerns their capacity to oxidize fatty acids. Under optimal conditions (in the presence of glucagon and an excess of carnitine), the refed cells (cells isolated from livers of rats fasted for 48 hr, and refed with carbohydrate for 48 hr) oxidized palmitate at approximately the same rate as fasted cells (cells isolated from livers of rats fasted for 48 hr). However, the refed cells still differed from fasted cells in that they required a much higher intracellular carnitine concentration and a higher palmitate concentration in the medium to reach the maximal level of oxidation. Carnitine decreased the intramitochondrial redox potential in the refed cells, which indicated more specific stimulation of β-oxidation. Glucagon increased the redox potential under all conditions used. Glucagon slightly stimulated carnitine transport into the cells and acetylcarnitine formation, and had a very pronounced stimulatory effect on the synthesis of long-chain acylcarnitines in refed cells. The level of total long-chain acyl coenzyme A (acyl-CoA) was increased by glucagon in refed cells. Carnitine increased the level of total long-chain acyl-CoA in fasted cells. It seems probable that, in the presence of glucagon, the extramitochondrial acyl-CoA level is increased, which may indicate direct inhibition of the triacylglycerol synthesizing enzymes. It is concluded that glucagon acts at least in part at one of the early stages in fatty acid metabolism, i.e., carnitine acyltransferase and/or glycerophosphate acyltransferase.

7445 THE INTERACTION OF QUATERNARY AMMONIUM COMPOUNDS WITH BILE SALTS. I. THE INTERACTION OF DODECYLTRIMETHYLAMMONIUM BROMIDE WITH SODIUM DEOXYCHOLATE. (Eng.) Kellaway, I. W.; Marriott, C. (Dept. Pharmacy, Univ. Nottingham, University Park, Nottingham, NG7 2RD, England). *Can. J. Pharm. Sci.* 12(3):70-73; 1977.

The interaction of dodecyltrimethylammonium bromide (C_{12}TAB) with sodium deoxycholate was investigated.

Although the interaction was examined in dilute solutions at an interface, the primary consideration was given to the bile salt concentrations above the critical micelle concentration, as bile salts exist in a micellar state in the gastrointestinal tract. C_{12}TAB was found to condense surface films of sodium deoxycholate. The critical micelle concentration of sodium deoxycholate was lowered in the presence of C_{12}TAB due to charge neutralization and "salting out" effects. The observed increase in micellar weight and dissymmetry may be explained in terms of mixed micelle formation. This hypothesis was confirmed by measuring the release of bound counter ions when C_{12}TAB was added to sodium deoxycholate.

7446 DIFFERENTIAL ACTIVATION OF RAT LIVER METHIONINE ADENOSYLTRANSFERASE ISOZYMES BY DIMETHYLSULFOXIDE. (Eng.) Hoffman, J. L.; Kunz, G. L. (Univ. Louisville Sch. Medicine, Louisville, KY 40201). *Biochem. Biophys. Res. Commun.* 77(4): 1231-1236; 1977.

The differential activation of rat liver methionine adenosyltransferase (MAT) isozymes by dimethyl sulfoxide (DMSO) is reported. At a concentration of 10%, DMSO stimulated one isozyme of rat liver MAT 50- to 70-fold when the assay was performed at a low (25 μM) methionine concentration. A second liver isozyme was stimulated only 1.5-fold. The more strongly stimulated liver isozyme eluted from diethylaminoethylcellulose and from Sephadex G-150 later than the less-sensitive (higher molecular weight) form. When rat liver, heart, brain, and kidney tissues were surveyed using DMSO activation of MAT in crude homogenates, only liver appeared to have the DMSO-activated isozyme. The ratio of DMSO-stimulated MAT activity/control MAT activity for rat liver tissue was 5.60, compared with ratios of 0.77, 0.58, and 0.75 for the heart, brain, and kidney, resp. Thus, the latter three tissues showed slight inhibition of MAT activity after DMSO treatment. The above results indicate that DMSO activation provides a simple test for determining the relative distribution of liver MAT isozymes.

7447 THE BIOCHEMISTRY OF THE REGENERATING LIVER. (Eng.) Lewan, L.; Yngner, T.; Engelbrecht, C. (Inst. Zoophysiology, Univ. Lund, Lund, Sweden). *Int. J. Biochem.* 8(7):477-487; 1977.

After partial hepatectomy, the remaining liver cells are rapidly depleted of glycogen and protein storage products, but they enlarge mainly because of accumulation of water and lipids. Protein and RNA metabolism change in order to initiate DNA synthesis and mitotic activity in the quiescent cells of the adult liver within 24 hr. The DNA concentration decreases during the prereplicative phase of liver regeneration because of the enlargement of the liver cells. DNA and RNA concentrations reach maximum levels after the wave of proliferation but before the accumulation of storage products. The protein concentration in the liver decreases by about 20% during the first day after partial hepatectomy and is not restored until 10-14 days thereafter, when liver regeneration is completed. Falling levels of serum albumin and blood glucose after partial hepatectomy show that the regenerating liver is unable to fulfill the secretory function of an intact liver. The factors initiating and regulating the regenerative growth of the liver after partial hepatectomy remain obscure.

7448 THE EFFECTS OF CHOLECYSTECTOMY ON THE BILE SALT POOL OF THE SYRIAN HAMSTER. (Eng.) Beher, W. T.; Lin, G. J.; Stradnieks, S.; Konde, W. N.; Rajan, K. S. (Henry Ford Hosp., 2799 W. Grand Blvd., Detriot, MI 48202). *Digestion* 15(4):338-347; 1977.

To clarify some aspects of cholecystectomy (CC), the half-life, distribution, size, and composition of the bile salt pool size was determined in intact and cholecystectomized Syrian hamsters. CC had no effect on the half-life of either the cholate or chenodeoxycholate pool. CC resulted in a significant ($p < 0.01$) shift in the distribution of bile salts from the gallbladder to the small intestine in fed animals. Fasting in intact hamsters resulted in a shift of bile salts ($p < 0.01$) from the small intestine, cecum, and liver to the gallbladder. However, even after a 48-hr fast, the small intestine contained 25.8% of the pool. In CC animals, fasting resulted in moderate but significant ($p < 0.01$) shifts of bile salts from the liver and small intestine to the cecum. CC had no significant effect on the size of the total bile salt pool in fed hamsters. The size of this pool was the same in fed and fasted intact hamsters; however, fasting in cholecystectomized hamsters resulted in a large decrease (37% to 66%, $p < 0.01$) in the pool. There was no significant difference in the bile salt pool composition of intact and cholecystectomized hamsters. Hamsters converted deoxycholate to cholate efficiently (78.3% to 91.6%), and the bile salts were recycled enterohepatically without dietary stimuli.

7449 STUDIES ON INCREASED BILE FORMATION PRODUCED BY POLYOXYBENZENES IN RATS. (Eng.) Tanayama, S.; Kanai, Y. (Medicinal Res. Lab., Takeda Chemical Industries, Ltd., Juso, Yodogawa-ku, Osaka 532, Japan). *Jpn. J. Pharmacol.* 27(1):71-78; 1977.

7452 CHANGES IN HEPATIC FATTY ACID DEGRADATION AND BLOOD LIPID AND KETONE BODY CONTENT

SECRETION AND METABOLISM

Intestine

7483 PERFUSION OF RABBIT COLON WITH RICINOLEIC ACID: DOSE-RELATED MUCOSAL INJURY, FLUID SECRETION, AND INCREASED PERMEABILITY. (Eng.) Gaginella, T. S.; Chadwick, V. S.; Debongnie, J. C.;

Lewis, J. C.; Phillips, S. F. (Coll. Pharmacy, Ohio State Univ., Columbus, OH 43210). *Gastroenterology* 73(1):95-101; 1977.

The effect of varying doses of ricinoleic acid perfused into rabbit colon was studied by measuring DNA recovery, fluid secretion, and changes in permeability and by electron microscopic observation of mucosal damage. The isolated colon of male New Zealand white rabbits that were anesthetized after fasting for 48 hr was perfused with 2.5, 5.0, 7.5, or 10 mM solutions of ricinoleic acid or a control solution buffered to pH 8 and with an osmolality of 294 mOsm/kg. Samples of effluents were collected 20 min after initiation of perfusion. DNA loss into the intestinal lumen increased with higher doses of ricinoleic acid. A dose-related increase in fluid secretion was observed with mucus in the effluent when the ricinoleate concentration was above 5 mM. Mucosal permeability increased with increasing concentration of ricinoleic acid as measured by the lumen to plasma flux of low molecular weight polyethylene glycols and the blood to lumen clearance of urea and creatinine. Ultrastructural study of colon samples from killed rabbits showed desquamation of surface epithelial cells after perfusion with ricinoleate but not after control solutions. The effects observed may explain the laxative action of ricinoleic acid, the active ingredient of castor oil.

7484 CYTOTOXICITY OF RICINOLEIC ACID (CASTOR OIL) AND OTHER INTESTINAL SECRETAGOGUES ON ISOLATED INTESTINAL EPITHELIAL CELLS. (Eng.) Gaginella, T. S.; Haddad, A. C.; Go, V. L. W.; Phillips, S. F. (Coll. Pharmacy, Ohio State Univ., Columbus, OH 43120). *J. Pharmacol. Exp. Ther.* 201 (1):259-266; 1977.

Epithelial cells were isolated from hamster small intestine and used to measure cytotoxicity *in vitro* of substances with laxative properties known to stimulate intestinal fluid secretion and to produce mucosal damage *in vivo*. The compounds included ricinoleic acid, dioctyl sodium sulfosuccinate, oleic acid, sodium deoxycholate, and sodium cholate. Cytotoxicity was assessed by (a) exclusion of trypan blue, (b) release of intracellular (prelabeled) ^{51}Cr, and (c) inhibition of cellular uptake of 3-*O*-methylglucose. Ricinoleate produced a dose-dependent (0.1-2.0 mM) cytotoxicity as assessed by all three methods. Oleic acid was less potent. The dihydroxy bile acid, deoxycholate, was equipotent with ricinoleate but its trihydroxy congener, cholate, was less potent. Dioctyl sodium sulfosuccinate had cytotoxicity similar in magnitude to that of ricinoleate and deoxycholate. The cytotoxicity of these agents to isolated cells may be related to their secretory potential *in vivo*, their abilities to produce structural change at the mucosal surface, and their laxative properties.

7485 CHARACTERIZATION OF BILE ACID BINDING TO RAT INTESTINAL BRUSH BORDER MEMBRANES. (Eng.) Wilson, F. A.: Treanor, L. L. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *J. Membr. Biol.* 33 (3/4):213-230; 1977.

The binding of bile acids to intestinal brush border membranes was characterized in rats. Total ^{14}C-taurodeoxycholate binding was similar for brush borders prepared from jejunum and ileum, linear with respect to monomer concentration, uninhibited by a structural analog, and not depressed by boiling or trypsin. A linear relationship existed between binding and the number of hydrogen bonds formed by a bile acid, and the slope of the line corresponded to $\delta \Delta F$ of 300 cal/mol. The binding of bile acids to the 105,000 x g supernatant fraction of sonicated brush borders was similar to the binding of phospholipid liposomes using gel chromatography. These data suggest that the kinetics and characteristics of binding of bile acid to ileal brush borders do not reflect the kinetics and characteristics of active ileal transport previously obtained in whole tissue preparations, but instead reflect those of passive jejunal transport. They also suggest that a determinant of binding is hydrogen bonding with water, that isolated intact brush borders are relatively polar membranes, and that binding to solubilized brush borders may represent partitioning between the aqueous phase and membrane lipid.

7486 THE EFFECT OF FATTY ACID PERFUSION ON INTESTINAL ALKALINE PHOSPHATASE. I. STUDIES ON MAN. (Eng.) Linscheer, W. G.; Malagelada, J. R.; Stolbach, L. L.; Fishman, W. H. (Veterans Admin. Hosp., 800 Irving Ave., Syracuse, NY 13210). *Am. J. Dig. Dis.* 22(6):509-515; 1977.

In 15 healthy subjects (13 men, 2 women) the release of intestinal alkaline phosphatase (IAP), sucrase, and glycylglycine dipeptidase (GD) into the lumen of an isolated segment of the small intestine was measured during fatty acid (FA) perfusion. The small intestine was isolated by a four-lumen, two-balloon tube technique and perfused with a control solution of sodium taurocholate (NaTC) or micellar solutions of FA (C8:0, C12:0, C18:1) in NaTC. Histochemical studies were performed on jejunal biopsies taken from six patients who had undergone Billroth II gastric resection to observe enzymes before and after perfusion with oleic acid (C18). In the healthy subjects, IAP release into bowel juice correlated directly with carbon-chain length of the FA in the perfusate. Sucrase concentration in bowel juice also increased during perfusion with C18:1 and C12:0, but not to the same extent as the IAP increase. GD release was negligible. In the six previously resected patients, IAP was observed by histochemical study of the jejunum to move from the brush border and Golgi region to the mucosal surface and lymph vessels after oleic acid perfusion. When staining for IAP and lipid was combined, it was found that enzyme activity was located in the same areas as fat particles. IAP probably moves from the brush border of the intestinal mucosa into the mucosal lymphatics via the same anatomical pathway as the long-chain triglycerides.

7487 THE EFFECT OF FATTY ACID PERFUSION ON INTESTINAL ALKALINE PHOSPHATASE. II. STUDIES ON THE RAT.

(Eng.) Malagelada, J. R.; Linscheer, W. G.; Fishman, W. H. (Mayo Clinic, Rochester, MI 55901). *Am. J. Dig. Dis.* 22(6): 516-523; 1977.

The translocation of intestinal alkaline phosphatase (IAP) and sucrase (S) in response to perfusion of intestinal loops with a wide range of fatty acids of different carbon chain lengths was studied in male Wistar rats. Perfusion solutions included a control solvent solution of sodium taurocholate (NaTC), a reference fatty acid solution of C18:1 in NaTC, and solutions containing either C16:1, C12:0, C8:0, or C6:0 in NaTC. Each of two adjoining loops of the proximal small intestine were perfused simultaneously with three solutions in random order. Fatty acid solutions induced the release of more enzyme into the intestinal lumen than did NaTC alone, and the relationship between enzyme release and fatty acid chain length was exponential. Histochemical studies of the intestinal mucosa before perfusion and after perfusion with NaTC or octanoic acid (C8) showed IAP in the brush border and Golgi region of the epithelial cells of the villi and crypts. After perfusion with oleic acid (C18), enzyme activity was markedly decreased in the brush border and Golgi region and was observed instead in small granules in the lumen of the intestine. Particles with high IAP activity were located in the same area as fat particles. The data indicate that IAP is associated with intestinal absorption of fat.

7488 SYNTHESIS OF COLLAGEN BY SMOOTH MUSCLE IN THE HYPERTROPHIC INTESTINE.

(Eng.) Gabella, G.; Yamey, A. (Dept. Anatomy, Univ. Coll. London, Gower St., London, England). *Q. J. Exp. Physiol.* 62(3):257-264; 1977.

Changes in the collagen content and concentration in the hypertrophic intestine of male guinea pigs were studied. The 50-mm segments of small intestine, at the oral side of an experimental stenosis, did not increase in length but underwent a sevenfold increase in weight. Segment weights ranged between 360 and 450 mg in the control intestine and about 3,250 mg in the experimental intestine. Collagen content was increased concomitantly; this increase was usually larger than the weight increase, and, therefore, the concentration of collagen is also increased. Total hydroxyproline content per 50-mm segment ranged from 190 to 620 µg in control animals from 1,150 to 5,500 µg in the hypertrophic intestine proximal to the stenosis. The hydroxyproline concentration (µg/mg wet weight) in segments along the length of the hypertrophic gut was greater than that in corresponding segments of control gut. The ratio of the increase in weight of collagen to that of non-collagenous material was greater in the longitudinal muscle than in the wall as a whole. Smooth sarcoplasmic reticulum was observed in control and hypertrophic smooth muscle cells. Cisternae of rough sarcoplasmic reticulum were more common in the hypertrophic muscle cells. It is suggested that some of the collagen is synthesized by the smooth muscle cells in the hypertrophic intestine.

7489 EX VIVO VASCULAR PERFUSION OF THE ISOLATED RAT SMALL BOWEL. IMPORTANCE OF THE INTESTINAL BRUSH BORDER ENZYME-RELEASE IN BASAL CONDITIONS.

(Eng.) Eloy, R.; Raul F.; Pousse, A.; Mirhom, R.; Anana, A.; Grenier, J. F. (Unite 61 de l'Inserm, Av. Moliere, 67200 Strasbourg/Hautepierre, France). *Eur. Surg. Res.* 9(2):96-112; 1977.

A technique for perfusion of the whole isolated intestine of the rat with homologous nondiluted blood is described. The intestinal enzyme and protein release, the hemodynamic vascular perfusion conditions, mechanical and electrical activities, and histological features of the *ex vivo* perfused rat intestine were compared with those of the intact intestine studied in anesthetized rats. No significant differences were noted in the two preparations except for the output of the intestinal brush border enzymes (sucrase, alkaline phosphatase, leucine aminopeptidase, and enterokinase) within the intestinal lumen. The intestinal enzyme output during *in vivo* experiments was usually constant or decreased slowly throughout the 2.5-hr perfusion. In the *ex vivo* 3-hr perfusion, enzyme output (except for alkaline phosphatase) and concentration increased. The early increase of intraluminal sucrase after only 95 min of perfusion indicates subcellular damage not detectable by other viability tests. It is suggested that release of brush border enzymes might be used as a criterion of function in intestinal preparations.

7490 IMMUNOFLUORESCENT LOCALISATION OF ENTEROKINASE IN HUMAN SMALL INTESTINE.

(Eng.) Hermon-Taylor, J.; Perrin, J.; Grant, D. A. W.; Appleyard, A.; Bubel, M.; Magee, A. I. (St. George's Hosp. Medical Sch., London SW17 0QT, England). *Gut* 18(4):259-265; 1977.

The distribution of enterokinase in human intestine was studied in operative mucosal biopsies using specific antiserum to human enterokinase that had been purified previously to apparent homogeneity by affinity chromatography and immunoabsorption. Fluorescence was observed in the brush border microvilli and glycocalyx of the intestinal epithelium in the duodenum and in the proximal 15 cm of jejunum distal to the duodenojejunal flexure. Fluorescence was maximal in the apical parts of the villi. The distal jejunum and ileum as well as the stomach and colon were consistently negative. Brunner's glands and goblet cells were never stained by specific antibody. Preliminary evidence was obtained that the human enterokinase molecule contains a specific antigenic determinant in its polypeptide component and a second determinant in the oligosaccharide moiety that cross-reacts with blood group A. Mucosal synthesis of enterokinase may be impaired in jaundice due to carcinoma of the pancreas and induced in the small intestine distal to the normal limit of synthesis after pancreaticoduodenectomy.

7491 PHOSPHATE-DEPENDENT GLUTAMINASE OF SMALL INTESTINE: LOCALIZATION AND ROLE IN INTESTINAL GLUTAMINE METABOLISM.

(Eng.) Pinkus, L. M.; Windmueller, H. G. (Nassau County Medical Center, East Meadow, NY 11554). *Arch. Biochem. Biophys.* 182(2):506-517; 1977.

The major glutamine-utilizing enzyme in the intestine, L-glutamine amidohydrolase, was identified and studied in detail. A highly active phosphate-dependent glutaminase was found in the mucosal epithelium of rats, dogs, cats, hamsters, rabbits, and monkeys (1.6-5.3 μmol/hr/mg of protein). The activity was lower in the mucosal epithelium of guinea pigs and chickens (0.3-1.4 μmol/hr/mg of protein). The net uptake of glutamine by intestine was greatest in those animals with the highest blood glutamine concentration and tissue glutaminase activity. The specific activity of the enzyme was similar in mucosa of rat duodenum, jejunum, and ileum (3.5-4.2 μmol/hr/mg of protein), but was less in rat stomach, cecum and colon (0.5-1.0 μmol/hr/mg of protein). The enzyme was found in both villus and crypt cells and was associated with mitochondria (57 to 66%). Though the enzyme appears similar in many respects to the phosphate-dependent glutaminase of kidney and brain, unlike the kidney enzyme, its activity was not induced during acidosis. The glutamine analogs, L-2-amino-4-oxo-5-chloropentanoic acid (chloroketone) and 6-diazo-5-oxo-L-norleucine (DON) caused an almost complete, irreversible inhibition of the enzyme activity *in vitro* (1-6% of control) and *in vivo*. Glutamine (100 mM) protected 50-60% of the activity against inhibition. Chloroketone administered luminally into a rat jejunal segment *in situ* resulted in 50% inhibition of glutaminase activity and totally inhibited the hydrolysis of glutamine subsequently absorbed from the lumen, however, the hydrolysis of glutamine taken up from arterial blood was not affected. DON administered arterially inhibited glutaminase almost completely and inhibited the hydrolysis of both luminal and arterial glutamine. It is suggested that metabolism of glutamine to glutamate occurs in mitochondria of both villus and crypt cells and that phosphate-dependent glutaminase in the major glutamine-utilizing enzyme of small intestine.

7492 IMMUNOCHEMICAL STUDIES ON THE SUBUNITS OF RABBIT-INTESTINAL SUCRASE-ISOMALTASE COMPLEX.

(Eng.) Takesue, Y.; Tamura, R.; Nishi, Y. (Res. Inst. Environmental Medicine, Nagoya Univ., Chikusa-ku, Nagoya, Aichi 464, Japan). *Biochim. Biophys. Acta* 483(2):375-385; 1977.

Antibodies specific for sucrase and isomaltase were prepared, and their effects on the enzyme activities and on the agglutination of microvillous vesicles were studied. Purified sucrase-isomaltase complex solubilized by papain from rabbit intestine was dissociated by citraconylation into its subunits, sucrase (specific activity 11.5 U/mg protein, recovery 23.5%) and isomaltase (specific activity 1.49 U/mg protein, recovery 18.5%). These subunits were then isolated in an immunologically and enzymatically active form by affinity chromatography on Sephadex G-200 and by gel filtration on Bio-gel P-300. Antibodies against the purified complex inhibited isomaltase but not sucrase and formed precipitation lines, crossing each other, with isolated sucrase and isomaltase, showing that the two enzymes differ in antigenicity from each other. By absorbing the antibodies with isolated sucrase and isomaltase, antibodies specific for isomaltase and sucrase, resp., were obtained. Similar to the original antibodies, both of the specific antibodies quantitatively agglutinated microvillous vesicles. Sucrase was not inhibited by either of the antibodies, whereas isomaltase was greatly inhibited by the isomaltase-specific antibodies, but not by the sucrase-specific types. The agglutination and inhibition curves of enzyme activity (sucrase or isomaltase) for trypsinized microvillous vesicles were the same as those for the control vesicles. The results indicate that the sucrase moiety is bound to the membrane through the isomaltase moiety.

7493 TRIGLYCERIDE EMULSIFICATION BY AMPHIPATHS PRESENT IN THE INTESTINAL LUMEN DURING DIGESTION OF FAT.

(Eng.) Linthorst, J. M.; Clark, S. B.; Holt, P. R. (Coll. Physicians and Surgeons, Columbia Univ., New York, NY 10027). *J. Colloid Interface Sci.* 60(1):1-10; 1977.

The emulsification of long-chain triglycerides may be an important preliminary step in overall intestinal fat absorption. To investigate this possibility, the capacity of amphipaths (bile salts, phosphatidylcholine, monolein, and oleic acid) normally present in the intestine for triglyceride emulsification was studied with the use of triolein as the test triglyceride. The triolein-amphipath mixtures were placed in tubes attached to a rack that turned at 60 revolutions/min, a rate that results in very low shear forces. The emulsions produced were studied for stability, particle size, and surface and interfacial tension. The bile salts sodium taurocholate, sodium glycodeoxycholate and glycochenodeoxycholate formed emulsions of low stability. Phosphatidylcholine and sodium oleate, at concentrations similar to those in the small intestine, produced emulsions of great stability. Monolein, a highly effective emulsifier under other physical conditions (sonication, homogenization), failed to emulsify triolein under low shear force. Addition of taurocholate to all other single amphipaths except for monolein resulted in a reduced emulsification of triolein. The combination of taurocholate and monolein, however, resulted in a spectacular increase in the quantity of triolein emulsified. The experiment indicates that at the usual pH of the small intestinal lumen (6.5), monoglyceride, fatty acid, and bile salt monomers interact to reduce the interfacial tension of an oil, allowing emulsification under conditions of low shear force.

7494 PURIFICATION OF HISTAMINE RECEPTOR (III): CHARACTERIZATION OF RECEPTOR RICH MEMBRANE FRACTION OF SMALL INTESTINAL SMOOTH MUSCLE OF

THE CAT. (Eng.) Uchida, M.; Takagi, K. (Dept. Molecular Pharmacology, Meiji Coll. Pharmacy, Setagaya-ku, Tokyo 154, Japan). *Jpn. J. Pharmacol.* 27(1):1-7; 1977.

The localization of specific histamine receptors was studied by investigating the distribution of marker enzymes in the receptor-rich subcellular fractions of the longitudinal smooth muscle of the feline small intestine. Histamine receptors were assayed by quantitation of the difference in binding of ^{14}C-dibenamine (4×10^{-6} M, 20 min at 37 C) alone, and in the presence of diphenydramine (10^{-6} M), which specifically blocks the receptor. A membrane enriched fraction (50,000 x *g*) at the top (1.1 g/cm^3) of a sucrose gradient was found to contain the highest ^{14}C-dibenamine binding activity (0.71 ± 0.06 nmol bound to receptors/mg protein) of all the fractions tested. This fraction was also enriched with the marker enzymes 5'-nucleotidase; true cholinesterase; Mg^{2+}-dependent ATPase; Na$^+$-, K$^+$-, Mg^{2+}-dependent ATPase; and Ca^{2+}-, Mg^{2+}-dependent ATPase, indicating that it consisted primarily of plasma membranes. Mitochondria-associated enzymes such as succinic dehydrogenase and cytochrome c oxidase were largely absent from the plasma membrane fraction. Lysosomal contamination (acid phosphatase) was negligible in the histamine receptor fraction. The overall chemical composition of the receptor-enriched fraction was protein (58.7%), phospholipid (30.8%), and cholesterol (6.7%) with traces of RNA (2.8%), hexosamine, and sialic acid (<1% each). Phosphatidylcholine comprised about 48.2% of the phospholipids. These results demonstrate that histamine receptors in the small intestinal smooth muscle of the cat are located on the cell membrane.

7495 IDENTIFICATION AND CHARACTERIZATION OF INTRINSIC FACTOR AND COBALOPHILIN FROM PIG ILEAL AND PYLORIC MUCOSA. (Eng.) Marcoullis, G.; Grasbeck, R.; Salonen, E. M. (Minerva Foundation Inst. Medical Res., P.O. Box 819, 00101 Helsinki 10, Finland). *Biochim. Biophys. Acta* 497(3):663-672; 1977.

Intrinsic factor and cobalophilin were isolated from pig ileal and pyloric mucosa and characterized. Ileal mucosa bound about 240 ng vitamin B_{12}/g and contained two vitamin B_{12}-binding proteins. One was highly active in the Schilling test, behaved immunologically as intrinsic factor, and was responsible for about half of the total vitamin B_{12}-binding capacity. The other binder was identified as cobalophilin (R-protein). Immunochemical purification of these proteins from pig ileum and pylorus was performed, and the molecular characteristics (sedimentation and diffusion coefficients, Stokes radii, frictional ratios, and molecular weights) of their vitamin B_{12} complexes were estimated. Isoelectric focusing revealed differences between the ileal and pyloric intrinsic factors but not between the cobalophilins. The mean isoelectric points of the pyloric and ileal intrinsic factors were pH 5.79 and 5.30, resp., whereas the corresponding figures for the cobalophilins were 4.13 and 4.10. The results of this and previous studies demonstrate that some intrinsic factor uncomplexed with vitamin B_{12} exists in the ileum of both man and pig.

7496 RAT INTESTINAL GLYCOLIPIDS. III. FATTY ACIDS AND LONG CHAIN BASES OF GLYCOLIPIDS FROM VILLOUS AND CRYPT CELLS. (Eng.) Bouhours, J. F.; Glickman, R. M. (Unite de Recherche de Physiopathologie Digestive, Hopital Edouard-Herriot, 69374 Lyon Cedex 2, France). *Biochim. Biophys. Acta* 487:51-60; 1977.

The fatty acids and long chain bases of the three major rat intestinal glycolipids (glucosylceramide, hematoside, and trihexosylceramide) were extracted and structurally identified to elucidate the differences between differentiated villus and immature crypt cells and the pathways of glycolipid biosynthesis. The glucosylceramide and the hematoside contained one part of normal for two parts of hydroxy fatty acids, while a reverse ratio was found in the trihexosylceramide. In villus cells, hydroxy fatty acids comprised approximately two-thirds of the total fatty acids in the glucosylceramide and hematoside and approximately one-third of the fatty acids in the trihexosylceramide. Behenic acid, the major fatty acid, comprised 18-22% of the nonhydroxy fatty acid weight of the villus glycolipids. In trihexosylceramide, arachidic acid and behenic acid were equally abundant. Trihexosylceramide contained about twice as much hydroxyarachidic acid as the other two major glycolipids. In glucosylceramide and hematoside, about 40% of the hydroxy fatty acids and 25% of the total fatty acids were hydroxylignoceric and hydroxynervonic acids. Thus, the glucosylceramide and hematoside of villus cells are similar, having a high proportion and similar distribution of hydroxy fatty acids, whereas the trihexosylceramide contains chiefly nonhydroxylated fatty acids plus large amounts of arachidic and hydroxyarachidic acids. Crypt cell glycolipids contained more arachidic and hydroxyarachidic acid than did villus cells, while villus cells glycolipids contained a higher proportion of oleic: stearic acid than crypt cells. Phytosphingosine formed 63-73% of the long chain bases in both villus and crypt cells. These results suggest that the hematoside and glucosylceramide may share a precursor, while trihexosylceramide may have a different lactosylceramide precursor. The significance of these results and their relationship to results from previous studies are discussed.

7497 THE INTESTINE AS A SOURCE OF APOLIPOPROTEIN A_1. (Eng.) Glickman, R. M.; Green, P. H. R. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *Proc. Natl. Acad. Sci. USA* 74(6):2569-2573; 1977.

The major apoprotein of CD strain rat mesenteric lymph chylomicrons was isolated and shown to be identical to apoprotein A_1 (apo A_1) isolated from serum high density lipoprotein (HDL). During intestinal lipid absorption, active synthesis of apo A_1 was demonstrated by radioactive amino acid incorporation into lymph chylomicron A_1 as well as lymph HDL.

Immunofluorescence studies of intestinal epithelium demonstrated a marked increase in apo A_1 fluorescence, confirming an active synthesis of this apoprotein during lipid absorption. Quantitative immunoelectrophoresis was used to measure apo A_1 in lymph and peripheral blood during various conditions designed to estimate the quantitative importance of intestinal apo A_1 relative to the levels of circulating lipoproteins. The proportion of lymph apo A_1 associated with lymph lipoproteins of density less than 1.006 g/ml increased from a basal level of 15.7 ± 1.9% to 46.2 ± 3.7% during lipid feeding. Thus, whereas in basal lymph most apo A_1 (84.5 ± 2.0%) was in the lipoproteins of density greater than 1.006 g/ml, lipid feeding caused a redistribution of lymph apo A_1 such that almost equal amounts of apo A_1 were found in the two different density fractions of lipoproteins. Biliary diversion, designed to eliminate intestinal lipoproteins of density less than 1.006 g/ml, resulted in a significant ($p<0.005$) decrease in serum apo A_1 levels from 51.6 ± 2.2 mg/100 ml to 42.6 ± 1.8 mg/100 ml. Plasma apo A_1 levels in nonlymph-diverted rats were significantly ($p<0.005$) increased by lipid feeding from 52.3 ± 2.1 mg/100 ml to 56.6 ± 2.0 mg/100 ml. The results indicate that the intestine actively synthesizes apo A_1 and is a significant source of this apoprotein for circulating lipoproteins.

7498 INTERACTIONS OF INTESTINAL LYMPH FLOW AND SECRETION. (Eng.) Granger, D. N.; Mortillaro, N. A.; Taylor, A. E. (Univ. Mississippi Sch. Medicine, Jackson, MS 39216). *Am. J. Physiol.* 232(1):E13-E18; 1977.

Isolated, vascularly perfused, cat ileal preparations were used to study the relationship between lymph flow and intestinal secretion under three experimental conditions: (1) decreased plasma colloid osmotic pressure induced by steady i.v. infusion of Tyrode solution (2.5 ml/min/kg), (2) rapid increase of intestinal venous pressure to 30 mm Hg, (3) exposure to cholera toxin solution (10 g/100 ml) for 1-2 hr. Lymph flow was measured in a large lymphatic vessel emerging from the mesenteric pedicle. Intestinal fluid was collected from an outflow cannula placed in the intestinal lumen, and it was assumed to represent secreted fluid. Under condition 1, peak lymph flow (38 times that of controls) occurred 60-90 min after the start of the Tyrode infusion. Lymph flow then decreased precipitously, accompanied by a rapid increase in intestinal secretion. Under condition 2, lymph flow peaked at 20 times that of controls within 10 min; it then diminished, accompanied again by increased intestinal secretion. Under condition 3, intestinal secretion increased but did not correlate with increase in lymph flow.

7499 INTESTINAL ASSIMILATION OF A TETRAPEPTIDE IN THE RAT: OBLIGATE FUNCTION OF BRUSH BORDER AMINOPEPTIDASE. (Eng.) Smithson, K. W.; Gray, G. M. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *J. Clin. Invest.* 60(3):665-674; 1977.

The intestinal assimilation of a mixed peptide, Gly-L-Leu-Gly-Gly, was studied using specific inhibitors of both peptide transport and the amino-oligopeptidases. Rat jejunum was used for *in vitro* gut sac and *in vivo* perfusion experiments with Gly-L-Leu-Gly-Gly (2 mM) as the test substrate. The tetrapeptide disappeared rapidly from the test solution (20 μmol/S/cm^2 *in vitro*; 17 μmol/S/cm^2 *in vivo*) by sequential removal of amino acid residues from the *N*-terminus to yield amino acids (glycine and leucine) and the C-terminal dipeptide (Gly-Gly). In gut sac experiments, 61-100% of these hydrolysis products appeared in the incubation medium and the remainder, in the tissue. Only small amounts (<39%) of hydrolytic products were found within the intestinal lumen *in vivo*. Gly-L-Pro (10 mM), a peptide known to be transported intact, failed to inhibit Gly-L-Leu-Gly-Gly disappearance, suggesting that the tetrapeptide does not use the intact transport mechanism. Hypoxic conditions (N_2 atmosphere) *in vitro* markedly inhibited ($p<0.005$) transport of glucose, leucine, and Gly-Gly but failed to impair Gly-L-Leu-Gly-Gly disappearance. Thus, hydrolysis of tetrapeptide does not depend on prior transport of the peptide and it does not occur by enzyme free in the medium. Disappearance of the tetrapeptide was blocked completely ($p<0.001$) by L-leucyl-β-naphthylamide (10 mM), a specific substrate for brush border aminopeptidase, and by the phthalimido derivative of L-leucine bromoethyl ketone, a potent peptidase inhibitor. Therefore, the amino-oligopeptidase at the intestinal surface appears to be essential for the initial stages of assimilation of this model tetrapeptide. Since intestinal surface digestion may be crucial to the assimilation of many peptide nutrients, it may be possible to identify patients with intestinal symptoms caused by a genetic defect in the brush border amino-oligopeptidase.

7500 THE EFFECT OF A SINGLE INJECTION OF HYDROXYUREA ON CELL POPULATION KINETICS IN THE SMALL BOWEL MUCOSA OF THE RAT. (Eng.) Al-Dewachi, H. S.; Wright, N. A.; Appleton, D. R.; Watson, A. J. (Dept. Pathology, Univ. Mosul, Mosul, Iraq). *Cell Tissue Kinet.* 10(3):203-213; 1977.

The effects of hydroxyurea (HU) on cell population kinetics in the rat jejunal crypt were studied by administering single i.p. injections (1,840 mg/kg) of HU to male Wistar rats. ^{3}H-thymidine (0.5 μCi/g, i.p., single injection) was given to some animals 1 hr prior to sacrifice and sections of the small bowel were then examined for histological changes; labeling and mitotic indices, the distribution of labeled and mitotic cells, and column count during the period 1-48 hr post-HU. Degenerative changes, localized in the proliferative portion of the crypt, were first observed 2 hr after HU administration, peaked at 7 hr, and were no longer apparent by 24 hr. The labeling and mitotic indices fell to zero by 1 and 3 hr after HU administration, resp. The cell number/crypt column fell from a control value of 32 ± 0.2 to 28.6 ± 0.2 by 10 hr after HU. After 10 hr, mitotic indices and the cell number rose rapidly to 40% and 8%, resp. (slightly higher than control values), by 20 hr and fell to control values by 30 and 32 hr post-HU, resp. At 10 hr, the percent of labeled cells was lowest (0-5%) at the most basal and the highest cell positions, and about 35% in the proliferative region of the crypt (control level was about 60%). By 13 hr, the labeling index in the proliferative zone had increased to 78% and reached a maximum of 80% by 20 hr. A second group of rats were given single i.p. injections of ^{3}H-thymidine (0.5 μCi/g) 15 hr post-HU; the fraction of labeled mitoses in axial sections of crypts was measured to determine the mean cycle times at various crypt cell positions for the next 28 hr. The mean cell cycle time for the whole crypt was 9.6 hr as compared with a control value of 11.3 hr; the change was due chiefly to the halving of the time of cell cycle phase G1. A third group of rats was given 1 mg/kg vincristine sulfate (VS) at 15 hr or 20 hr post-HU; the numbers and positions of mitotic nuclei were quantified in axially sectioned crypts every 15 min for 2.5 hr following versus administration. At 15 hr, there was an increase in cell birth rate in the basal portion of the crypt with smaller values in the proliferative compartment and a second peak at cell positions 13-17; by 20 hr, cell birth rates were high throughout the proliferative compartment. The mechanism of action of HU is discussed. The results suggest that basal crypt cells, which were not as severely affected by HU due to their normally long cell cycle times, were responsible for the repopulation of the damaged proliferative cell region.

7501 COMPENSATION BY THE RESIDUAL INTESTINE AFTER INTESTINAL RESECTION IN THE RAT. I. INFLUENCE OF AMOUNT OF TISSUE REMOVED. (Eng.) Hanson, W. R.; Osborne, J. W.; Sharp, J. G. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439). *Gastroenterology* 72(4):692-700; 1977.

To determine whether there is a pattern to the adaptive response seen in residual intestine following increasing amounts of intestinal resection, several cell kinetic parameters were investigated in the residual intestine 30 days after the resection of 10-80% of the mid-small intestine (excluding the duodenum) in male Holtzman rats. The degree of intestinal response increased in a stepwise fashion as the amount of tissue removed was increased. The response involved marked increases in DNA synthesis per crypt (expressed as disintegrations per minute of tritium and reflecting [^{3}H]thymidine incorporation), cells per crypt column, ^{3}H-labeled cells per crypt column, cells per villus column, and thickness of all intestinal wall components. These changes occurred throughout the small intestine even at lesser resections. "Crypt profiles" reflected changes in cell counts, but when the labeling frequency of proliferative cells was expressed as a percentage of the total crypt height, there was no change. The total number of crypts in the duodenum remained unchanged and the total number of crypts in the residual jejunum plus ileum decreased proportionally to the amount of tissue removed. Intestinal compensation occurs by increasing the size of the structures present in the residual intestine, not by increasing the number of structural units.

7502 INFLUENCE OF THE THYROID HORMONE ON THE MATURATION OF THE SMALL INTESTINE. (Eng.) Moog, F. *In: Gastrointestinal Development and Neonatal Nutrition. 7508 THE EFFECT OF AN ANTACID ON THE BIOAVAILABILITY OF INDOMETHACIN. (Eng.)

Galeazzi, R. L. (Inselspital, CH-3010 Bern, Switzerland). *Eur. J. Clin. Pharmacol.* 12(1):65-68; 1977.

The bioavailability of indomethacin from two indomethacin-antacid (aluminum hydroxide magnesium carbonate and magnesium hydroxide) combinations was compared with the bioavailability of p.o. indomethacin in a double blind crossover study of 12 healthy subjects. Relative bioavailability was estimated by three methods: comparison of plasma concentrations at various times, comparison of areas under plasma concentration time curves, and comparison of the amount of drug excreted unchanged in the urine. The combination with the slightly smaller amount of antacid (preparation A) showed significantly decreased bioavailability by all three methods in comparison with indomethacin alone (preparation C). The combination with the larger amount of antacid (preparation B) was also less bioavailable than preparation C. This effect was significant only for the comparison of areas under curves and not for plasma levels, although the mean plasma levels produced by preparation B at all times were lower than those for preparation C. These findings suggest that aluminum hydroxide magnesium carbonate and magnesium hydroxide decrease the bioavailability of indomethacin.

7509 THE RELATION BETWEEN THE INTESTINAL MICROFLORA AND INTESTINAL PARAMETERS IN MICE.

(Eng.) Koopman, J. P.; Janssen, F. G. J.; van Druten, J. A. M. (Central Animal Lab., Catholic Univ. Nijmegen, Geert Grooteplein N 29, Nijmegen, Netherlands). *Z. Versuchstierkd.* 19(1/2):54-61; 1977.

In mice with different microfloras, the relative cecal weight (RCW), pH and oxidation-reduction potential in the cecum, and fecal *Escherichia coli* concentration after a p.o. dose of 10^5 *E. coli* cells were measured to determine if these parameters could be used to assess the normalization of germfree (GF) Swiss mice after association with certain microfloras. The following groups of mice were examined: GF mice, GF mice associated with one anaerobic bacterial strain (GF + 1), GF mice associated with seven anaerobic strains (GF + 7), GF mice associated with a complete culture of colonization-resistance-factor flora (GF + CRF), and GF mice associated with a partial CRF (GF + partial CRF). In addition, ND_2 mice with CRF microflora (CRF), SPF C_3H/StZ mice (SPF), SPF C_3H/StZ mice that had been cecectomized (SPF-cecum), and conventional $C_{57}BL/Rij$ mice were used. Fecal *E. coli* concentration and RCW were the most suitable parameters for assessing the normalization of GF mice (SPF and conventional mice used as the norm). When the RCW's of *E. coli*-untreated GF, CRF, SPF, and conventional mice were compared, GF mice possessed the highest RCW (about 6%), whereas the other three groups had RCW's of <2.5%. When the RCW's were measured 14 days after a p.o. *E. coli* dose, GF mice again had the highest RCW (about 6.5%), followed by GF + 1 mice (about 5.5%), GF + partial CRF mice (about 3%), GF + CRF mice (about 2.75%), CRF mice (2.5%), SPF mice (<2%), and GF + 7 mice (<2%). GF mice contained 10^{10}-10^6 *E. coli*/g feces, but SPF mice contained $<10^2$ *E. coli*/g. GF mice and GF + 1 mice did not show significantly different *E. coli* fecal concentrations, but those of GF + 7 mice were significantly lower. GF + CRF and GF + partial CRF mice had lower fecal *E. coli* concentrations than GF + 7 mice, and CRF mice showed a higher concentration than GF + partial CRF and GF + CRF mice. SPF-cecum mice had remarkably higher fecal *E. coli* concentrations than SPF mice. Contact with *E. coli* increased RCW in GF, CRF, and SPF mice, although the effect for GF mice was less clear than that for the other two groups.

7510 FECAL FLORA OF MAN. V. FLUCTUATION OF THE FECAL FLORA OF HEALTHY ADULTS. (Ger.)

Mitsuoka, T.; Ohno, K. (Inst. Physical and Chemical Res., Wako-shi, Saitama, 351, Japan). *Zentralbl. Bakteriol.* [*Orig. A*] (238):228-236; 1977.

Seven fecal samples were taken from each of six healthy men at 10-day intervals over a 3-month period and analyzed bacteriologically to determine possible individual and temporal variations. All subjects ate their usual diet during the experiment. *Bacteroidaceae*, *Catenabacterium* (eubacterium and anaerobic lactobacillus), *Peptostreptococcus* (anaerobic gram-positive coccus), and *Lactobacillus bifidus* constituted the predominant floras in all subjects. *Spirillaceae*, *Megasphaerae*, and *Clostridium* (except *Cl. perfringens*) also predominated, but only in certain individuals. *Enterobacteriaceae* and *Streptococcus* constituted the accompanying (secondary) floras in all persons, *Veillonella* and *Lactobacillus* in some persons. The residual floras, which consisted of *Cl. perfringens*, *Staphylococcus*, and yeast, were small and they occurred only occasionally, in low numbers. The overall bacterial count was constant in all persons, averaging 1-3 x 10^{11}/g. The number of bacteria in the predominant flora group was also fairly constant in the same person, but there were greater individual variations with respect to the type of flora: each person had a specific individual fecal flora. There were considerable variations in the numbers of bacteria of the accompanying and residual flora groups.

7511 DEPRESSION OF LACTOSE HYDROLYSIS BY YEASTS.

(Eng.) Berman, D. A.; Sobieski, R. J. (Dept. Biology, Wichita State Univ., Wichita, KS 67208). *J. Med. Microbiol.* 10(3):373-376; 1977.

The depression of lactase activity by pathogenic and nonpathogenic yeasts was studied in rabbits. *Candida albicans* strain 1 and strain 2, and *Saccharomyces cerevisiae* all significantly depressed the activity of β-galactosidase in intestinal loops; the percentage depression by the respective yeasts were 99%, 99%, and 87% at 4 C immediately and 75%, 74%, and 62% after 75 min at 22 C. These results indicate that yeasts bind the enzyme without undergoing active metabolism or requiring prolonged contact. Depression of β-galactosidase activity by dead cells of *C. albicans* strain 526 was similar to that produced by living cells; in four experiments, the percentage reductions in activity by autoclaved cells were 42%, 44%, 32%, and 58%, while the corresponding figures for living cells were 37%, 44%, 27%, and 52%. The possibility that the depression of lactase activity is involved in the virulence of *C. albicans* seems remote, as *S. cerevisiae* (which is rarely pathogenic), also possessed a significant degree of inhibitory activity.

7512 ANTIPROLIFERATIVE ACTIVITY OF ANTI-INFLAMMATORY DRUGS IN TWO MAMMALIAN CELL CULTURE LINES.

(Eng.) Hial, V.; De Mello, M. C. F.; Horakova, Z.; Beaven, M. A. (Natl. Heart, Lung, and Blood Inst., Bldg. 10, Rm. 5N107, Bethesda, MD 20014). *J. Pharmacol. Exp. Ther.* 202(2):446-454; 1977.

The inhibition of rat hepatoma cell and human fibroblast proliferation and metabolism by anti-inflammatory drugs was studied. Indomethacin, phenylbutazone, aspirin, and sodium salicylate inhibited cell proliferation in a dose-dependent manner. The inhibition was reversible; normal growth resumed when the cultures were washed free of drug. Protein and nucleic acid synthesis, as measured by isotope incorporation, was also reduced, although this reduction was probably a reflection of the decrease in cell numbers. An exception was that, in low concentrations, salicylamide, salicylic acid, and aspirin stimulated protein and nucleic acid synthesis, but in high concentrations (>1 mM) they inhibited culture growth as well as protein and nucleic acid synthesis. Pharmacologically inactive derivatives, such as *m*-hydroxybenzoic acid and gentisic acid, were not inhibitory in concentrations up to 5 mM. The order of potency in inhibiting culture growth, meclofenamate>indomethacin>salicylamide>phenylbutazone>phenacetin>aspirin=salicylic acid, was similar to that reported for their anti-inflammatory activity and their ability to inhibit prostaglandin synthesis. The antiproliferative activity of these drugs may, in part, account for their anti-inflammatory and toxic actions *in vivo*.

7513 FLUORESCENCE HISTOCHEMICAL STUDIES ON SEROTONIN IN THE SMALL INTESTINE AND THE INFLUENCE OF VAGAL NERVE STIMULATION.

(Eng.) Ahlman, H. (Dept. Surgery III, Univ. Goteberg, Sweden). *Acta Physiol. Scand.* (Suppl. 437):1-30; 1976.

Studies were carried out to determine (a) the effect of extrinsic denervation of the small intestine on bowel function and on monoamine (MA)-containing structures in the intestinal wall of the cat, (b) the possible presence of 5-hydroxytryptamine (5-HT) in nerve fibers of the guinea pig myenteric plexus, (c) the effect of efferent cervical vagal nerve stimulation on 5-HT content in feline enterochromaffin cells, (d) the transmittor mechanism involved in the vagal control of 5-HT in enterochromaffin cells of the cat, and (e) the presence of catecholamine (CA) fibers at different levels in vagal nerves of the cat and man. Extrinsic denervation of the small intestine of long-term surviving cats totally abolished all CA terminals in the wall of the intestine, but no functional changes were observed. The number and the fluorescence intensity of enterochromaffin cells seemed to be unchanged. These results indicate that the extrinsic nerves are not necessary for adequate bowel function. The myenteric plexus of the guinea-pig, when studied before and after reserpine and monoamine oxidase inhibition, was found to contain only CA fluorescence. No evidence for the presence of 5-HT in the nerves of the plexuses was obtained. The intracellular concentration of 5-HT in feline small intestinal enterochromaffin cells, when estimated by a cytofluorimetric method, was clearly reduced by efferent cervical vagal nerve stimulation. The results support the hypothesis of a neurogenic release of 5-HT from enterochromaffin cells. Cholinergic blockade with atropine did not block the vagally induced decrease of 5-HT in the enterochromaffin cells. However, propranolol and adrenergic denervation at the cervical level of the vagal nerves, i.e., removal of the superior cervical ganglia, both blocked this effect; no change in 5-HT fluorescence was induced by nerve stimulation after such pretreatment. Phenoxybenzamine caused *per se* a marked increase in 5-HT fluorescence. The results support the hypothesis of a vagal adrenergic release of 5-HT from enterochromaffin cells and suggest that β-receptor activation is responsible for this release. Whether α-receptors are also involved in the 5-HT release could not be judged. In both cats and man, efferent CA containing nerve fibers were present in the vagal nerve. At the cervical level of cat vagal nerve, many adrenergic axons, originating in the superior cervical ganglia, were observed. At the subdiaphragmatic level, CA-fibers were present, which seemed to originate from other ganglia. In man, the main trunk at the subdiaphragmatic level, as well as the nerve of Latarjet, contained numerous CA-fibers.

7514 GUT-ASSOCIATED LYMPHOEPITHELIAL TISSUE: BIDIRECTIONAL TRANSPORT OF TRACER BY SPECIALIZED EPITHELIAL CELLS ASSOCIATED WITH LYMPHOID FOLLICLES.

(Eng.) Bockman, D. E.; Stevens, W. (Medical Coll. Georgia, Augusta, GA 30902). *J. Reticuloendothel. Soc.* 21(4):245-254; 1977.

Horseradish peroxidase (HP) was used as a tracer to determine whether its transmission through follicle-associated epithelium (FAE), an area of specialized epithelium covering the luminal pole of lymphoid follicles in gut-associated lymphoepithelial tissues, is bidirectional. After the i.v. or intracardiac (i.c.) injection of HP, peroxidase activity was localized in mouse Peyer's patches, rabbit appendix, and chicken bursa of Fabricius using standard techniques. The reaction product was localized in much greater quantities in FAE than in generalized epithelium. The transmission of HP into the lumina of the rabbit appendix and the chick bursa was demonstrated by the presence of peroxidase activity in saline washings from these cavities 15 min after i.c. administration of the tracer. After the injection of HP into the lumen of the bursa of Fabricius of six chickens, the greatest localization of peroxidase activity was in the tufts of FAE that separate the lymphoid follicles from the lumen. Lesser quantities of reaction product were present over the total lymphoid follicle. Reaction product was also much more prominent in FAE of mouse Peyer's patches than in the general epithelium covering the villi after 1 hr of intraluminal HP. It is concluded that FAE is capable of efficient bidirectional transport of macromolecules, some of which may participate in the immunologic activity of gut-associated lymphoepithelial tissues.

7515 ALCOHOL AND BLOOD LIPIDS: THE COOPERATIVE LIPOPROTEIN PHENOTYPING STUDY. (Eng.) Castelli, W. P.; Gordon, T.; Hjortland, M. C.; Kagan, A.; Doyle, J. T.; Hames, C. G.; *et al.* (Natl. Heart, Lung, and Blood Inst., Landow Bldg., Room C841, 7910 Woodmont Ave., Bethesda, MD 20014). *Lancet* 2(8030):153-155; 1977.

Blood lipids and alcohol consumption were studied in five different populations. Alcohol consumption was positively correlated with high-density lipoprotein cholesterol level in all populations (r=0.16-0.30), the lipid level appearing to be a graded response even over the low levels of alcohol consumption reported. Less strong but consistently negative correlations were found with low-density lipoprotein cholesterol. Plasma triglycerides showed a modest positive correlation with alcohol.

7516 INHIBITORY EFFECT OF FUMARIC ACID AND DICARBOXYLIC ACIDS ON GASTRIC ULCERATION IN RATS. (Eng.) Kuroda, K.; Akao, M. (Res. Inst. Chemobiodynamics, Chiba Univ., Chiba, Japan). *Arch. Int. Pharmacodyn.* 226(2):324-330; 1977.

DIAGNOSTIC PROCEDURES

7525 EVALUATION OF RAST AS AN IMMUNOLOGICAL METHOD FOR DIAGNOSIS OF MULTILOCULAR ECHINOCOCCOSIS. (Eng.) Ito, K.; Horiuchi, Y.; Kumagai, M.; Ueda, M.; Nakamura, R.; Kawanishi, N.; *et al.* (Dept. Medicine and Physical Therapy, Faculty Medicine, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan). *Clin. Exp. Immunol.* 28(3):407-412; 1977.

A radioallergosorbent test (RAST), which is widely used for detecting IgE antibodies, was used for the diagnosis of multilocular echinococcosis. Antigen material for the test was obtained from alveolar hydatid cysts grown in the peritoneal cavity of experimentally infected cotton rats. The paper disc method of RAST was used, in which one piece of antigen-coupled paper disc was put into 0.05 ml of 10 times diluted serum, shaken gently for 24 hr at 4 C, and washed three times with incubation buffer (0.3% bovine serum albumin and 0.1% Tween 20 in phosphate-buffered saline of pH 7.4). This paper disc was then put into 0.05 ml of ^{135}iodine-labeled anti-IgE (60,000 counts/min), shaken, and washed as mentioned above. Radioactivity of the paper disc was counted by a gammacounter. A positive RAST reaction was defined as more than 1.5 times the mean count obtained with 100 normal sera. A positive RAST was observed in 30 of 34 patients with multilocular echinococcosis and in only 7 of 52 individuals who did not have radiological evidence of the disease but who showed a positive reaction to one or more of the following tests: complement fixation test (CFT), indirect hemagglutination test (IHA), and immunoelectrophoresis test (IE). The difference in RAST counts between these two groups was highly significant ($p<0.001$). The accuracy of RAST was 87%, which is comparable to IHA (87%) and IE (89%) and much higher than for CFT (60%). When RAST was combined with IE and CFT or with IHA, IE, and CFT, the accuracy of diagnosis was increased to 97%.

7526 THE SMALL BOWEL ENEMA: EXPERIENCE WITH 150 EXAMINATIONS. (Eng.) Sanders, D. E.; Ho, C. S. (Toronto General Hosp., 101 College St., Toronto, Ontario M5G 1L7, Canada). *Am. J. Roentgenol.* 127(5):743-751; 1976.

Antegrade small bowel barium enemas were successfully performed in 150 patients; in 10 patients with ileostomies, the barium was administered retrograde through the ileostomy. Indications for small bowel enema included Crohn's disease (89 patients), small bowel obstruction (37), bleeding (12), fistula (5), abdominal pain (2), carcinoid tumor (2), possible lymphoma (1), and malabsorption (2). The results of the procedure showed normal bowel (94 patients), Crohn's disease (37), small bowel obstruction (7), fistula (5), malrotation (2), and jejunal carcinoma, carcinoid tumor, ischemic ileitis, post bulbar ulcer, and malfunctioning ileostomy (1 each). The results of recent conventional small bowel studies were compared with those of the small bowel enema in 26 patients. All lesions observed with conventional studies were also observed with the enema method. Pathology observed at biopsy, surgery, or autopsy was correlated with x-ray results in 15 patients. All but two preoperative radiological diagnoses were confirmed by the pathological studies. These two patients had normal x-ray findings, although one had disseminated carcinomatosis, and the other had Crohn's disease of the ileum. Four representative case reports are included. There were no major side-effects of the procedure. Occasional nausea and vomiting were attributed to the presence of the tube in the stomach, and transient diarrhea occurred if there was a fluid overload of the small bowel. The small bowel enema is the preferred procedure for the assessment of suspected small bowel disease.

7527 COLOSCOPY IN THE DIAGNOSIS OF INFLAMMATORY DISEASES OF THE LARGE INTESTINE. (Ita.) Rossini, F. P.; Ferrari, A. (Ospedale Maggiore di S. Giovanni Battista e della Citta di Torino, Turin, Italy). *Minerva Med.* 67(7):429-432; 1976.

Inflammatory diseases of the colon were found in 493/3,000 patients examined by colonoscopy. A definitive diagnosis was possible in 440 of the 493 cases. Included in these 440 diagnoses, in order of prevalence, were idiopathic ulcerations of the colon and rectum, Crohn's disease, diverticulosis, actinic colitis, mycosis, transitory ischemic colitis, pseudomembranous colitis, tuberculosis, and amebiasis. The remaining cases were grouped as unclassified inflammation of the colon. Description of the endoscopic findings is given for each one of these diseases with emphasis upon the primary diagnostic finding. Colonoscopy has a negligible risk with infrequent complications and is invaluable in the differential diagnosis of inflammatory bowel disease.

7528 DIAGNOSTIC SIGNIFICANCE OF FASTING SERUM BILE ACID IN LIVER DISEASE. (Eng.) Hirayama, C.; Irisa, T.; Arimura, K.; Nakamura, M. (Second Dept. Internal Medicine, Tottori Univ., Yonago 683, Japan). *Acta Hepatogastroenterol.* 23(6):385-391; 1976.

Total serum bile acids was evaluated in 21 healthy subjects and 100 patients with liver disease; extraction was obtained using Amberlite XAD 2 followed by enzymatic and fluorimetric assays, and the diagnostic significance of serum bile acid determination was assessed. The normal value for fasting serum bile acid was 3 ± 2 μM. The serum bile acid level was markedly raised early in the course of acute viral hepatitis, subsequently fell rapidly before resolution of biochemical tests, and was elevated again in relapse. In chronic liver disease, the serum bile acid level was elevated moderately and correlated roughly with disease severity. The serum bile acid level correlated significantly with serum bilirubin, BSP retention, and other liver function tests, with the exception of serum cholesterol. The fasting serum bile acid level is a reliable screening test for a variety of liver diseases. It is useful in assessing functional and morphological hepatic impairment.

7529 LIMITATIONS OF ANGIOGRAPHIC DIFFERENTIAL DIAGNOSIS IN MAJOR HEPATIC PROCESSES. (Eng.) Gutierrez, O. H.; Rosch, J. (Univ. Oregon Health Sciences Center, 3181 S.W. Sam Jackson Park Rd., Portland, OR 97201). *Fortschr. Roentgenstr.* 127(1) 1-8; 1977.

Eleven cases in which hepatic angiography failed to be useful in the diagnosis of liver diseases are reviewed. These cases occurred in a series of 183 consecutive hepatic angiograms in patients with proven hepatic pathology. The angiographic diagnosis was incorrect in four patients and of no value in the differential diagnosis in the remaining seven. In one patient, a hepatocellular carcinoma was misdiagnosed as a liver abscess. In a 3-week-old infant, a liver cyst was thought to be a liver tumor. In the third patient, angiography suggested the presence of a liver neoplasm, but laparotomy revealed micronodular cirrhosis and acute alcoholic hepatitis. In the fourth patient, angiography suggested the presence of metastases from a gastric reticulum cell sarcoma, but multiple multilocular abscesses were found at autopsy. In four patients, enlarged intrahepatic ducts could not be distinguished from liver metastases, and in the remaining three patients, angiography was not useful in distinguishing between acute non-neoplastic processes (i.e., viral hepatitis, recurrent regenerating cirrhosis, and liver necrosis) and tumor metastases. Methods for minimizing diagnostic failure with angiography include infusion angiography and pharmacoangiography.

7530 LIVER AND SPLEEN SCANNING AS A USEFUL DIAGNOSTIC TEST IN THE MANAGEMENT OF LIVER TRAUMA IN YOUNG PATIENTS. (Eng.) Ell, P. J.; Beck, E.; Meixner, M. (Middlesex Hosp. Medical Sch., Mortimer St., London, WIN 8 AA, England). *Fortschr. Roentgenstr.* 127(2):123-126; 1977.

The cases of 11 patients, aged 4-23 yr, in whom liver and spleen scanning with gamma camera was useful in the management of blunt abdominal trauma are summarized. Seven patients had a positive liver and/or spleen scan. No false-negative scan results were obtained. Scans were carried out postoperatively in eight cases, and no false-positive results were obtained in any of these; follow-up scans demonstrated healing. In two cases, the scans revealed no filling defects; surgery was avoided, and the patients recovered without surgical intervention. Liver and spleen scanning is a safe, rapid, and noninvasive diagnostic procedure, and it yields useful information, both pre- and postoperatively.

7531 EARLY EXPERIENCE WITH THE VARIAN SIX SECOND BODY SCANNER IN THE DIAGNOSIS OF HEPATOBILIARY TRACT DISEASE. (Eng.) Harell, G. S.; Marshall, W. H., Jr.; Breiman, R. S.; Seppi, E. J. (Stanford Univ. Medical Center, Stanford, CA 94305). *Radiology* 123(2):355-360; 1977.

The diagnostic efficacy of computed tomography (CT) with the use of the Varian Six Second (VSS) body scanner was evaluated in 34 patients with various liver lesions. Each patient was first radiographed with lead markers taped to the back along the midscapular line to provide a reference level. Scans were then obtained at intervals of approximately 2.5 cm from the top of the right hemidiaphragm to several centimeters below the free edge of the liver. Contrary to previous reports, almost two-thirds of the patients had heterogeneous CT appearance in normal liver tissue. Small oval or Y-shaped areas with lower CT numbers than the surrounding liver parenchyma were correlated with portal vein branches in most cases, with hepatic veins or other parts of the portal triad in the others. These regions could be distinguished from metastases, which in most cases had a more circular appearance. CT appeared to be a reliable indicator of chronic obstructive jaundice, early common bile duct obstruction, and diffuse hepatic diseases. The ability of the scan to differentiate a fluid-filled cyst or abscesses from solid tumors was an important advantage of CT over radionuclide techniques.

GASTROINTESTINAL DISEASES

ESOPHAGUS

7554 LOWER ESOPHAGEAL SPHINCTER IN REFLUX ESOPHAGITIS. (Eng.) Scheurer, U.; Halter, F. (Univ. Hosp., Inselspital, 3010 Berne, Switzerland). *Scand. J. Gastroenterol.* 11(6): 629-634; 1976.

Lower esophageal sphincter pressure (LESP) was studied by intraluminal perfusion manometry in the resting state and after graded i.v. doses of pentagastrin in 12 healthy subjects and 27 patients with reflux esophagitis. Eleven patients had ulcerative esophagitis, and 16 had nonulcerative esophagitis, as determined by the histological examination and endoscopic appearance of the inflamed mucosa. The length of the lower esophageal sphincter (LES) was similar in patients and controls. A correlation was found between the magnitude of mean basal end expiratory (mbe) LESP value reduction and the grade of esophageal mucosa inflammation. The lowest mbe occurred in patients with ulcerative esophagitis. It was significantly different from that of patients with nonulcerative esophagitis ($t=3.37$, $p<0.01$). Both values were significantly reduced from that of the controls ($t \geq 2.50$, $p<0.0125$). The responsiveness of the LES to i.v. pentagastrin was quantitatively reduced throughout the whole range of the dose response curve in patients with ulcerative esophagitis, whereas patients with nonulcerative esophagitis only differed in the maximum mbe pressure value from the controls. Four patients showed a paradoxical pressure decrease to i.v. pentagastrin, resulting in a LESP reduction to 8% of the mbe LESP. The i.v. injection of secretin or cholecystokinin led to a similar reaction of the LES in these patients.

STOMACH

567 STOMACH CANCER AMONG HAWAIIANS AND CAUCASIANS IN HAWAII. (Eng.) Wronkowski, Z.; temmermann, G.; Rellahan, W. (Inst. Oncology, Wawelka 15, 00-973, Warsaw, Poland). *Cancer* 39(5):2310-316; 1977.

he ethnic distribution of stomach carcinoma in awaii was studied from a sample of 288 Caucasian nd Hawaiian patients observed between 1960 and 972. There were 232 histologically confirmed carinomas, 114 in Caucasians and 118 in Hawaiians. ost of the Hawaiians were partly Caucasian (32.1%) r partly Chinese (34.3%); 33.6% were pure Hawaiian r a mixture with other racial groups. Diffuse arcinoma (Lauren's classification) was more freuent in women and younger patients, and there were ore long-term survivors among women than among men. ntestinal-type carcinoma was more prevalent in lder patients and men, and it carried a more avorable prognosis than the diffuse type. The ntestinal:diffuse type ratio was 1.12:1 among aucasians and 1.20:1 among Hawaiians, compared to .76:1 among Hawaii Japanese. There was no apparnt association between this ratio and the cancer isk in any of these populations. Prognosis was ot associated with the level of cancer risk. The awaiians shared a high risk with the Japanese and poor prognosis with the Caucasians. An unexpected inding was that 33% of the Caucasian patients with tomach cancer had Portuguese surnames, but Poruguese subjects comprise only 10% of the Caucasian opulation of Hawaii. They are in the lower socioconomic stratum of Caucasian society. This study dentified the Portuguese as another Hawaiian poplation at high risk of stomach cancer.

568 A MODIFIED LEUCOCYTE MIGRATION ASSAY AS INDICATOR OF MALIGNANT AND NON-MALIGNANT ASTRIC MUCOSAL ALTERATION. (Eng.) Zoller, M.; atzku, S.; Rapp, W.; Schulz, U. (German Cancer Res. enter, Im Neuenheimer Feld 280, D-6900 Heidelberg , W. Germany). *Digestion* 15(5):373-384; 1977.

he leukocytes of patients with various gastric ucosal alterations were exposed to normal gastric mucosal extracts and to gastric tumor extracts to correlate the clinical and histological status of patients with leukocyte migration (LM) reactivity. Positive LM reactivity (pathological migration index with at least 3/5 tumor extracts) was observed in 32/35 operable gastric cancer patients before surgery and in 36/39 patients with inoperable gastric cancer. At postoperative times of 10-14 days, 2 weeks to 2 months, 2-6 months, 6 months to 1 yr, and 1+ yr, positive LM reactivity was seen in 26/29, 8/9, 3/16, 1/11, and 3/33 operable gastric cancer patients, resp., who had no symptoms of cancer. Positive LM reactivity was observed in four of five patients surgically treated for gastric cancer who had local recurrences or metastases at 1+ yr after surgery. Among patients with nonmalignant gastric diseases (superficial, interstitial, or atrophic gastritis and duodenal or gastric ulcer), positive LM reactivity against tumor extracts was associated almost exclusively with atrophic gastritis, with and without intestinal metaplasia (24/43 cases). When LM reactivity was tested with a normal gastric mucosal extract, a pathological migration index was generally found only in patients who exhibited positive reactivity with tumor extracts. Among 68 gastric cancer patients who were positive with tumor extracts, 12 showed a pathological migration index with normal gastric mucosal extracts; all 30 patients with nonmalignant gastric diseases who exhibited positive reactivity with tumor extracts were reactive with the normal gastric mucosal extract. When exposed to tumor extracts, the leukocytes of the cancer patients were inhibited four times more frequently than enhanced; in patients with nonmalignant gastric diseases, inhibition was observed less often than enhancement. The reverse was found when reactivity with normal gastric mucosal extracts was tested. The above findings suggest that the LM assay could be valuable for gastric cancer detection.

7572 NOCTURNAL METIAMIDE TREATMENT IN THE MANAGEMENT OF HEALED DUODENAL ULCERATION. (Eng.) Thompson, M. H.; Venables, C. W.; Smith, P. A.; Walker, W. (Royal Victoria Infirmary, Newcastle upon Tyne, England). *Gut* 18(6):438-441; 1977.

Sixteen duodenal ulcer patients were investigated in double-blind trial to determine whether the administration of a nocturnal dose of metiamide would prevent or delay the relapse of duodenal ulceration after initial ulcer healing. Eight patients received metiamide (400 mg, p.o.) at bedtime, and eight received placebo for 12 months. Endoscopically confirmed duodenal ulcer relapses occurred in two of eight on metiamide and six of eight on placebo. When the length of remission in each group was compared with the period of relapse, there was a highly significant prolongation of remission in the patients treated with metiamide; the total number of patient weeks in remission and in relapse in the metiamide-treated group were 240 and 55 weeks, resp., while the corresponding figures in the placebo-treated group were 156 and 128 weeks, resp. ($p<0.001$). There was also a reduction in the extent and severity of duodenitis in the metiamide-treated patients. The results show that nocturnal therapy with metiamide reduces the number of duodenal ulcer relapses and significantly increases the length of remission in this disease.

7573 THERAPEUTIC TESTING BY ACETAZOLAMIDE IN THE DIFFERENTIATION OF A BENIGN FROM A MALIGNANT NICHE. (Eng.) Puscas, I.; Veress, S.; Resiga, C. (Str. Dunarii 28, 4775 Simleu-Silvaniei jud. Salaj, Rumania). *Acta Hepatogastroenterol.* 24(3):205-209; 1977.

The therapeutic value of acetazolamide in gastric ulcer, and its use in differentiating between benign and malignant conditions, was studied in 741 patients with radiologically confirmed gastric ulcer. Acetazolamide (25-30 mg/kg) was administered p.o. daily, together with 3 g sodium bicarbonate, 1 g potassium bicarbonate, and 1.5 g magnesium oxide. The size of the ulcer crater was considerably reduced after 7-9 days of treatment with acetazolamide; the crater disappeared in 2-3 weeks. This favorable result was obtained without a special diet or rest. In 38 patients in whom there was no significant radiologic change after acetazolamide treatment, malignancy of the ulcer crater was confirmed. Acetazolamide is useful in the differentiation between benign and malignant ulcer craters.

7574 THE EFFECT OF VAGOTOMY ON THE LOWER OESOPHAGEAL SPHINCTER: A MANOMETRIC STUDY. (Eng.) Angorn, I. B.; Dimopoulos, G.; Hegarty, M. M.; Moshal, M. G. (Dept. Surgery, Univ. Natal, Durban, South Africa). *Br. J. Surg.* 64(7): 466-469; 1977.

The pressure profile of the gastroesophageal sphincter was studied at rest and during abdominal compression in 16 normal controls, 9 controls with duodenal ulcer awaiting operation, and 26 duodenal ulcer patients after subdiaphragmatic truncal vagotomy with a drainage procedure. An "early" group of 9 patients was investigated 10-14 days after surgery and a "late" group of 17 patients more than 1 yr after operation. The resting lower esophageal sphincter pressures after vagotomy in both the early and late groups were similar to the levels of sphincter pressure in the controls. However, the increase in sphincter pressure always observed during abdominal compression in normal subjects was significantly decreased by complete vagotomy, and the normal increase in the gastro-sphincteric pressure gradient was not produced. All 26 patients were tested for completeness of vagotomy using the insulin/pentagastrin test. In 19 patients, the vagotomy was complete and in 7 patients it was judged to be incomplete. A decrease in the gastro-sphincteric pressure gradient on manometric study of the lower esophageal sphincter was interpreted as indicating complete vagotomy. Accurate correlation between secretory response and compression response was achieved in all patients with complete vagotomy and in five of the seven patients with incomplete vagotomy. The results indicate that some test of vagal innervation should be carried out after every vagotomy.

7606 BARIUM STUDIES IN SMALL-BOWEL INFARCTION. (Eng.) Joffe, N.; Goldman, H.; Antonioli, D. A. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Radiology* 123(2):303-309; 1977.

The diagnostic efficacy of the barium examination was studied in seven patients with proved intestinal infarction. The primary presenting symptoms were abdominal pain and mild gastrointestinal bleeding in six patients and intestinal obstruction symptoms in one. Four main patterns of radiological abnormality of the affected small bowel loops were observed: slight to moderate dilatation with thickening of the mucosal folds; spasm and irritability with a more or less uniform scalloping of the bowel; moderate dilatation with a smooth or finely serrated contour and complete effacement of the mucosal pattern; and marked dilatation and flaccidity with evidence of gross ulceration. Immediately after radiography, the patients underwent surgical resection. In two patients, the necrosis was limited to the mucosa, but five patients had transmural infarction. Comparison of the radiographic and pathological findings showed that with the former, only three patients were evaluated correctly with regard to the integrity of the bowel wall. In addition, the radiographic findings failed to predict nonviability of the bowel in four of five patients with transmural infarction.

7607 ISCHAEMIC STRICTURES OF THE SMALL INTESTINE IN NIGERIA. (Eng.) Subbuswamy, S. G.; Iweze, F. I. (Dept. Pathology, Univ. Benin, Benin City, Nigeria). *Gut* 18(4):266-273; 1977.

The clinical and pathological features of eight cases of ischemic small intestinal stricture are reported. In five cases, the ischemia was related to inguinal hernia, with herniorrhaphy a few weeks before surgery for stricture in four cases. The prominent symptoms were postprandial abdominal pain, weight loss, and constipation. The mucosal surface underlying the strictures showed transverse ulcers involving the entire intestinal circumference. The ulcers showed highly vascular granulation tissue with a diffuse nonspecific chronic inflammatory infiltrate, in which a number of hemosiderin-laden histiocytes were seen. The mucosa surrounding the ulcers showed loss of the villous pattern, increased numbers of goblet cells, branching of glands, and pyloric metaplasia. Atherosclerotic narrowing of arteries could have been responsible for the ischemia in three cases. The most important factor in making a clinical or pathological diagnosis of ischemic stricture of the small intestine appears to be awareness of the condition. The importance of studying the mesentery, with particular attention to lymph nodes and blood vessels, before making a final diagnosis on intestinal lesions is emphasized.

7608 ANGIOGRAPHIC DIAGNOSIS OF INTRINSIC DUODENAL INFLAMMATORY DISEASE. (Eng.) Glickman, M. G.; Itzchak, Y. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Radiology* 123(2):297-302; 1977.

The efficacy of angiography for differentiating between pancreatic and peripancreatic lesions was evaluated in seven patients with duodenal inflammation. The histological diagnosis, made by surgical exploration in six patients and endoscopic biopsy in one, were ruptured duodenal diverticulum with periduodenal inflammation in one patient, chronic periduodenal inflammation due to prior perforation of a duodenal ulcer in five, and duodenal inflammation due to acute pancreatitis in one. Angiographic distinction between the pancreatic and duodenal processes was made preoperatively in all patients. In the six patients with inflammatory disease due to a primary duodenal process, arterial abnormalities (arterial displacement, hypervascularity, contour irregularities) affected the arterial branches that supplied the duodenum, while the pancreatic arteries had a normal appearance. In the patient with pancreatitis, abnormalities were present in both the pancreatic and duodenal arteries. Attention to the shape and direction of vascular displacement and to separate evaluation of pancreatic and duodenal arteries will help to distinguish duodenal from pancreatic disease.

7609 PLASMA LEVELS AND INTESTINAL ABSORPTION OF 25-HYDROXYVITAMIN D IN PATIENTS WITH SMALL BOWEL RESECTION. (Eng.) Compston, J. E.; Creamer, B. (St. Thomas' Hosp., London, England). *Gut* 18(3):171-175; 1977.

Plasma levels of 25-hydroxyvitamin D (25-OHD) and intestinal absorption of 25-hydroxyvitamin D$_3$ (25-OHD$_3$) were investigated in 38 patients (25 women and 13 men; mean age, 41.9 yr) who had undergone some form of small bowel resection. The mean plasma 25-OHD level for these patients was 9.9 ± 0.86 ng/ml (range, 1.3-24.1 ng/ml) compared with a mean level of 18.3 ± 0.9 ng/ml (range, 11.0-29.7 ng/ml) for controls ($p < 0.0005$). Plasma levels of 25-OHD in these patients after a p.o. dose of 25-OHD$_3$ (10 μg/kg) were also reduced in relation to controls, with mean values at 4, 8, and 24 hr after 25-OHD$_3$ administration being 78.8 ± 9.5 (range, 32-140), 87.1 ± 6.7 (range, 56-136), and 69.4 ± 7.0 (range, 32-117) ng/ml, resp., for patients with small bowel resection compared with corresponding mean values of 124.6 ± 5.4 (range, 78-155), 135.6 ± 6.3 (range, 103-186), and 93.8 ± 6.8 (range, 56-143) ng/ml, resp., for controls. Although the dietary intake of vitamin D tended to be low in many patients (mean, 1.75 μg/day versus a recommended daily intake of 2.5 μg/day), seasonal variations of plasma 25-OHD levels indicated normal exposure to sunlight for most of the patients studied. It is suggested that these observations provide some evidence for malabsorption of 25-OHD after small bowel resection, and it is postulated that this may be due to interruption of the enterohepatic circulation of bile acids and 25-OHD. These factors may contribute to the low plasma levels of 25-OHD found in the patient group.

SMALL INTESTINE

Malabsorption

7633 ACRODERMATITIS ENTEROPATHICA: II. ZINC DEFICIENCY AND ULTRASTRUCTURAL FINDINGS. (Eng.) Braun, O. H.; Heilmann, K.; Rossner, J. A.; Pauli, W.; Bergmann, K. E. (Kinderklinik des Stadt. Krankenhauses, Kanzlerstr. 2-6, D-7530 Pforzheim, W. Germany). *Eur. J. Pediatr.* 125(2):153-162; 1977.

Clinical and ultrastructural findings in two siblings suffering from acrodermatitis enteropathica (AE) who were treated with zinc sulfate therapy are reported. The basic defect in AE is zinc deficiency caused by zinc malabsorption. Both patients were originally treated with oxyquinolines for an extended period of time with varying clinical success. The daily p.o. administration of zinc sulfate in various forms at doses ranging from 110-220 mg/day resulted in a permanent clinical remission, with normalization of serum zinc levels. Zinc concentration in the hair was not significantly correlated with the type of therapy used in these patients. Prior to zinc sulfate therapy, Paneth cells in the jejunal mucosa of these patients contained pleomorphic, irregular granules with an inhomogeneous matrix and showed confluence of the granules with the formation of giant granules. The Paneth cells also displayed fibrillar cytoplasmic inclusions. Jejunal biopsies, taken 9 and 13 months after zinc substitution was started and at a time when serum zinc levels were normal, revealed an almost complete normalization of the pathology of Paneth cells; Paneth cell granules at this time showed only slight pleomorphy, the matrices were homogeneous, there were no inclusions, and there were no giant granule formations. It is concluded that pathologic changes in Paneth cells in AE are the result and not the cause of zinc deficiency.

7634 JEJUNAL MUCOSAL IMMUNOGLOBULINS AND COMPLEMENT IN UNTREATED COELIAC DISEASE. (Eng.) Scott, B. B.; Scott, D. G.; Losowsky, M. S. (St. James' Hosp., Leeds, England). *J. Pathol.* 121 (4):219-223; 1977.

The basement membrane and lamina propria of jejunum specimens of treated and untreated patients with celiac disease were examined for extracellular immunoglobulin and complement. Immunofluorescence studies showed that there was a significantly increased incidence of extracellular IgA and complement in the basement membrane zone and lamina propria of untreated adult celiac patients compared to celiac patients on a gluten-free diet. IgG was also demonstrated with complement, particularly in the untreated patients. These findings, taken together with those of other studies, suggest that a local antibody-antigen reaction involving IgA and complement may be responsible for the ongoing mucosal damage in untreated celiac disease as well as for the acute damage following gluten challenge of the treated patient. Furthermore, consequent upon this damage there may be a secondary IgG antibody response, possibly reticulin antibody, contributing to the mucosal damage.

7635 DNA-SYNTHESIZING CELLS IN THE BLOOD IN COELIAC DISEASE AND INFLAMMATORY BOWEL DISEASE. (Eng.) Holmes, G. K. T.; Bratt, P. M.; Ling, N. R.; Cooke, W. T. (Selly Oak Hosp., Birmingham B29 6JD, England). *Clin. Exp. Immunol.* 28 (3):484-489; 1977.

DNA synthesis was studied in the blood of 63 patients with celiac disease, 35 patients with inflammatory bowel diseases, and 9 controls. The level of ^{3}H-labeled thymidine ([^{3}H]TdR) incorporation of blood cells of patients with celiac disease was shown, in two separate studies, to be significantly lower than that of the normal control group. In the first study, the "background" DNA synthesis in unstimulated cultures containing a standard number of blood lymphocytes was measured on days 4, 5, and 6. In the second study, a standard volume of freshly drawn whole blood was added to culture medium, and the [^{3}H]TdR incorporation was measured over the first 24 hr and from 48 to 72 hr. In all cases, the [^{3}H]TdR incorporation of cells of celiac patients on a normal or a gluten-free diet was lower than that of the control group. It is suggested that sequestration of DNA-synthesizing cells in the mucosa of the small bowel may partly explain these results. In whole-blood cultures from patients with inflammatory bowel disease in remission, [^{3}H]TdR incorporation over the first 24 hr was raised in Crohn's disease but normal in ulcerative colitis.

7636 THE GASTROINTESTINAL ABSORPTION OF PENICILLIN V IN CHILDREN WITH SUSPECTED COELIAC DISEASE. (Eng.) Bolme, P.; Eriksson, M.; Stintzing, G. (Dept. Pediatrics, St. Goran's Hosp., Box 12500, S-112 81 Stockholm, Sweden). *Acta Paediatr. Scand.* 66(5):573-578; 1978.

The gastrointestinal absorption of penicillin V (pc-V) was studied in 13 infants with a long history of diarrhea and clinical manifestations of malabsorption. Calcium pc-V was given after at least 2 hr of fasting in a dose of 20 mg/kg, p.o.; absorption was evaluated by measuring the plasma concentration of pc-V at 30-min intervals for 3 hr. An age-matched group of children who were being treated with pc-V for an upper respiratory tract infection served as controls. After they were subjected to an initial diagnostic examination, the diarrhea patients underwent a small bowel biopsy. They could be divided into two groups: (1) six patients with provisional diagnosis of celiac disease and (2) seven patients in whom diagnosis of celiac disease could be ruled out. The plasma concentration of pc-V in group 1 was significantly lower than that in controls, but the children in group 2 showed no significant impairment of pc-V absorption. The gastrointestinal absorption of calcium pc-V in the group 1 patients gradually improved after they were fed a gluten-free diet. After 6-8 months, the plasma concentration of pc-V showed a definite normalization in three of six patients. The variability in the results stresses the importance of clinical symptoms rather than the result of an absorption test in the diagnosis of celiac disease.

7637 EFFECT OF ORAL AMINO ACID SUPPLEMENTATION ON LIVER DISEASE AFTER JEJUNOILEAL BYPASS FOR MORBID OBESITY. (Eng.) Lockwood, D. H.; Amatruda, J. M.; Moxley, R. T.; Pozefsky, T.; Boitnott, J. K. (Univ. Rochester, Sch. Medicine and Dentistry, 601 Elmwood Ave., Rochester, NY 14642). *Am. J. Clin. Nutr.* 30(1):58-63; 1977.

In an attempt to prevent liver disease, six morbidly obese patients were orally supplemented with essential amino acids for 4 months after jejunoileal bypass. Amino acid supplementation only partially influenced protein malnutrition and had no effect on deterioration of hepatic morphology and dysfunction. Although this mode of therapy appears to be ineffective in preventing postoperative liver abnormalities, other studies suggest that oral oligopeptide supplementation and parenteral administration of amino acids are beneficial.

7638 PATHOPHYSIOLOGY AND SIGNIFICANCE OF MALABSORPTION AFTER ROUX-EN-Y RECONSTRUCTION. (Eng.) Bradley, E. L., III; Isaacs, J. T.; Del Mazo, J.; Hersh, T.; Chey, W. Y. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *Surgery* 81(6):684-691; 1977.

Metabolic studies were conducted in five patients after total gastric resection with Roux-en-Y reconstruction and in five normal controls to determine the nutritional consequences of this particular technique of restoring gastrointestinal continuity. Malabsorption of fat (19.2 ± 2.2%) and nitrogen (22 ± 2.5%) in the study patients was moderate but significantly ($p<0.01$) greater than in normal controls; the absorptive loss was approximately three times the normal values. However, positive nitrogen balances (+0.33 ± 0.18 g/day) were maintained in the study patients, suggesting that malabsorption after the above surgical technique is not usually of clinical significance. The study patients exhibitied a significantly lower average jejunal concentration of lipase (5.0 ± 1.8 Teitz

U/cm^3, $p<0.01$) and trypsin (6.5 ± 1.8 μg/cm^3, $p<0.001$) than did controls (lipase and trypsin values of 37.4 ± 8.1 Teitz U/cm^3 and 162.7 ± 39.6 μg/cm^3, resp.) over a 60-min postcibal period. Also, the concentrations of lipase and trypsin were lower at each point in time in study patients versus controls. The maximum concentration of lipase and trypsin achieved in study patients occurred 30-60 min after ingestion of the test meal, thereby effectively preventing proper concentrations of pancreatic enzymes from reaching ingested food in the jejunum. Malabsorption of fat and nitrogen in study patients improved after exogenous pancreatic enzyme administration but not after the administration of tetracycline. Bacterial overgrowth as a cause of postoperative malabsorption thus may be less important than previously thought. It is suggested that malabsorption after total gastric resection with Roux-en-Y reconstruction is due primarily to maldigestion brought about by duodenal bypass that, in turn, results in either an absolute or a relative pancreatic enzyme insufficiency.

LARGE INTESTINE

7657 ANGIODYSPLASIA AS A SOURCE OF INTESTINAL BLEEDING. (Eng.) Marx, F. W., Jr.; Gray, R. K.; Duncan, A. M.; Bakhtiar, L. (10921 Wilshire Blvd., Los Angeles, CA 90024). *Am. J. Surg.* 134(1):125-130; 1977.

Selective mesenteric angiography was performed in seven patients with hematochezia of obscure origin. Six had histories of repeated hemorrhages for as long as 5 yr. Three patients had undergone surgery (splenectomy, vagotomy-antrectomy, or vagotomy-pyloroplasty followed by exploratory laparotomy and, later, transverse colostomy) in unsuccessful attempts to control the bleeding. In all patients, the cause of the hematochezia was identified by mesenteric angiography as angiodysplasia. In two additional patients, an area of angiodysplasia was accidentally discovered at preoperative diagnostic aortography for an aortic aneurysm. The site of the abnormality was the cecum in seven of nine, the cecum and jejunum in one, and the midileum in one. One patient, who also had lung cancer and suspected brain metastases, was treated only by transfusions; there was one more hemorrhage before his death from cancer 10 months later. The affected bowel was resected in the other symptomatic patients, and they had no further episodes of hemorrhage. The patients with fortuitously discovered angiodysplasia and no histories of gastrointestinal hemorrhage showed no evidence of hematochezia after resection of their aneurysms.

7658 LIVER METASTASIS OF COLON ADENOCARCINOMA DEMONSTRATED ON ^{99m}Tc-PYROPHOSPHATE BONE SCAN. (Eng.) Stevens, J. S.; Clark, E. E. (Portland Adventist Medical Center, 10123 SE Market, Portland, OR 97216). *Clin. Nucl. Med.* 2(8):270-271; 1977.

The case of a patient with colon adenocarcinoma in whom a ^{99m}Tc-sulfur colloid liver scan showed a large focal defect due to a metastasis is presented. A ^{99m}Tc-pyrophosphate bone scan showed no osseous abnormality, but incidentally labeled the liver metastasis. Neither the primary colon tumor nor the liver metastasis showed evidence of calcification or ossification. There was a desmoplastic response with abundant mature and immature collagen in the primary tumor and in the metastasis, suggesting that the mechanism of the ^{99m}Tc-pyrophosphate labeling may have been related to the presence of collagen.

7659 METABOLIC EPIDEMIOLOGY OF COLON CANCER: FECAL BILE ACIDS AND NEUTRAL STEROLS IN COLON CANCER PATIENTS AND PATIENTS WITH ADENOMATOUS POLYPS. (Eng.) Reddy, B. S.; Wynder, E. L. (American Health Foundation, Valhalla, NY 10595). *Cancer* 39(6):2533-2539; 1977.

Because of the potential significance of cholesterol (Ch) metabolites and bile acids in the pathogenesis of colon cancer, fecal neutral sterols and bile acids were determined in 99 adults of both sexes. There were 31 patients with untreated colon cancer, 13 with adenomatous polyps, 9 with other digestive diseases (spastic colon, rectal ulcer, Crohn's colitis, irritable colon, or diverticulosis), and 34 normal subjects, all American Caucasians consuming a mixed Western diet. There were also 12 Japanese controls who consumed at least two Japanese meals a day. The patients with colon cancer or adenomatous polyps showed higher fecal levels of Ch, coprostanol, coprostanone, total bile acids, deoxycholic acid, and lithocholic acid than either normal control group. The patients with other digestive diseases and the American controls had similar results. The Japanese controls (a low-risk population for colon cancer) showed significantly lower levels of fecal bile acids and Ch metabolites than the American controls (a high-risk population). The results suggest that possible interactions between bile acids and Ch metabolites and the colonic epithelium may be relevant in colon carcinogenesis.

7660 AN UNUSUAL ALIMENTARY DUPLICATION. (Eng.) Bedford, A. F. (Westminster Children's Hosp., England). *Br. J. Clin. Pract.* 31(6):76-77; 1977.

The case of a 6-yr-old boy with a colonic duplication cyst is presented. The patient presented with paraumbilical pain associated with a gradual increase in abdominal girth; there was no change in bowel habit. Radiologic studies demonstrated large bowel displacement and the presence of a colonic mass that did not fill with contrast medium. At laparotomy, a 16 x 13 x 10 cm cyst was found attached to the antimesenteric border of the colon; it was attached by a pedicle that had undergone three turns. The cyst was thin walled, contained dark-brown fluid, and was supplied by large branches of the inferior mesenteric vessels; these vessels did not supply the adjacent bowel. The cyst was removed by ligating the vessels and resecting the colon to which the cyst was attached. The cyst fulfilled two of three previously proposed criteria for alimentary duplication, i.e., it was adherent to some part of the gastrointestinal tract, and it contained smooth muscle in its wall. However, the presence of an alimentary mucous membrane could not be confirmed. The attachment of the cyst to the antimesenteric border of the colon is unusual, and a blood supply separate from that of the adjacent bowel has not been previously described.

7661 INTESTINAL OBSTRUCTION CAUSED BY AN ABERRANT UMBILICAL VEIN. (Eng.) Svendsen, L. B.; Johansen, T. S.; Kristensen, P. (Hvidovre Hosp., Kettegard Alle 30, 2650 Hvidovre, Denmark). *Acta Chir. Scand.* 143(3):191-192; 1977.

The case of a 31-yr-old woman with intestinal obstruction associated with an aberrant umbilical vein is reported. The patient had a 9-yr history of recurrent abdominal pain and obstipation. Laparotomy revealed that the umbilical vein was positioned in such a way that it compressed both the transverse colon and the terminal ileum against the abdominal wall.

7662 PREOPERATIVE ORAL ANTIBIOTICS REDUCE SEPTIC COMPLICATIONS OF COLON OPERATIONS: RESULTS OF PROSPECTIVE, RANDOMIZED, DOUBLE-BLIND CLINICAL STUDY. (Eng.) Clarke, J. S.; Condon, R. E.; Bartlett, J. G.; Gorbach, S. L.; Nichols, R. L.; Ochi, S.; *et al.* (Surgical Service [112], Veterans Admin. Hosp., Wood, WI 53193). *Ann. Surg.* 186(3):251-259; 1977.

The effectiveness of short-term, low dose, preoperative p.o. administration of neomycin (1.0 g) and erythromycin base (1 g) combined with vigorous purgation in reducing the incidence of wound infections and other septic complications of elective colon and rectal operations was studied in a prospective, randomized, double-blind trial of 116 patients. All patients received mechanical preparation; 56 received neomycin-erythromycin base while 60 received placebo. The two patient groups were comparable in age distribution, clinical diagnoses, associated systemic diseases, types of operation performed, and similar clinical features. The overall rate of directly related septic complications was 43% in the placebo group and 9% in the group receiving neomycin and erythromycin base. The wound infection rates were 35% in placebo and 9% in antibiotic treated patients. The p.o. administration of neomycin and erythromycin base together with vigorous mechanical cleansing reduces the risk of septic complications after elective colorectal operations.

7663 COMPARISON OF CATGUT AND POLYGLYCOLIC ACID SUTURES IN COLONIC ANASTOMOSES. (Eng.) Clark, C. G.; Wyllie, J. H.; Haggie, S. J.; Renton, P. (Univ. Coll. Hosp. Medical Sch., University St., London WCIE 6JJ, England). *World J. Surg.* 1(4): 501-506; 1977.

The use of catgut sutures was compared with that of polyglycolic acid sutures in a randomized prospective trial of patients undergoing colonic surgery. In all cases, the sutures were used for the all-coats layer in a two-layer anastomosis, where the seromuscular layer was interrupted silk. When polyglycolic acid sutures were used, only 8 95 anastomoses leaked, whereas when catgut was used, 24 of 99 anastomoses leaked; this difference was significant at the 1% level (Chi square=7.7). The leakage rates were 36.2% on the left side of the colon and 5.4% on the right side when catgut was used, compared with 14.3% on the left and 0% on the right using polyglycolic acid ($p<0.05$). Eleven (5.7%) of the patients died; the anastomosis was performed with catgut in seven and polyglycolic acid in four. In four patients in the catgut group and in two in the polyglycolic acid group, the deaths could be attributed primarily to breakdown of the anastomosis. The results suggest that if colonic anastomoses are to be made by a two-layer technique, the use of polyglycolic acid sutures is superior to that of catgut sutures.

7664 A CONTROLLED COMPARISON OF ONE- AND TWO-LAYER TECHNIQUES OF SUTURE FOR HIGH AND LOW COLORECTAL ANASTOMOSES. (Eng.) Goligher, J. C.; Lee, P. W. G.; Simpkins, K. C.; Lintott, D. J. (General Infirmary, Leeds, England). *Br. J. Surg.* 64(9):609-614; 1977.

A controlled trial of one- and two-layer inverting techniques of suture for the construction of high and low colorectal anastomoses was conducted on 137 patients. The integrity of the suture lines was assessed clinically and by routine radiological examination after a Gastrografin enema. Anastomotic leakage was diagnosed clinically in nine patients, but subclinical dehiscence was demonstrated radiologically in a further 39 patients. There was a slightly greater incidence of dehiscence after the one-layer technique of suture for both high and low anterior resection.

7665 ADENOCARCINOMA OF THE COLON PRESENTING AS ANAEMIA. (Eng.) Hall, J.; Hare, J.; Douglas, M. (Austin Hosp., Heidelberg, Victoria 3081, Australia). *Med. J. Aust.* 2(2):61-62; 1977.

LARGE INTESTINE

Ulcerative Colitis

7717 FECAL BILE ACIDS AND CHOLESTEROL METABOLITES OF PATIENTS WITH ULCERATIVE COLITIS, A HIGH-RISK GROUP FOR DEVELOPMENT OF COLON CANCER. (Eng.) Reddy, B. S.; Martin, C. W.; Wynder, E. L. (American Health Foundation, Valhalla, NY 10595). *Cancer Res.* 37(6):1697-1701; 1977.

Fecal neutral steroids and bile acids were measured in 15 patients with ulcerative colitis, 15 family controls who were immediate relatives of patients, 15 patients with other digestive diseases, and 40 healthy unrelated controls. The mean fecal excretion of cholesterol, coprostanol, and cholestane-3β-5α,6β-triol was higher in patients with ulcerative colitis (12.5 ± 2.9, 26.6 ± 7.0, 0.3 ± 0.02 mg/g dry feces) than in other groups ($p<0.05$). Patients with other diseases, family controls, and unrelated controls excreted comparable levels of neutral sterols. Patients with ulcerative colitis excreted levels of bile acids in their feces comparable to those excreted by other groups. Since patients with chronic ulcerative colitis are at an increased risk of developing colon carcinoma, these findings suggest that possible interactions between cholesterol metabolites and colonic epithelial cells may be relevant in colon carcinogenesis.

7718 INDICES OF GRANULOCYTE ACTIVITY IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Koldkjaer, O.; Klitgaard, N. A.; Schmidt, K. G. (Odense Univ. Hosp., DK-5000 Odense, Denmark). *Dan. Med. Bull.* 24(2):72-76; 1977.

Four parameters reflecting granulocyte activity were investigated in cases of ulcerative colitis and Crohn's disease: plasma and neutrophil lysozyme concentration, neutrophil alkaline phosphatase activity, and Nitro Blue Tetrazolium (NBT) reducing capacity of neutrophils. Sixty-five untreated patients were investigated, 35 with ulcerative colitis, 14 with hemorrhagic proctitis, and 16 with Crohn's disease. Patients with active ulcerative colitis and severe Crohn's disease showed the most pronounced signs of granulocyte activity. The differential diagnosis between ulcerative colitis and Crohn's disease based on plasma lysozyme measurements was not possible. Severe cases of ulcerative colitis and Crohn's disease were distinguishable from the other patient groups by the neutrophil/plasma lysozyme concentration ratio. Adding the results of the alkaline phosphatase measurements and the NBT-test was valuable in identifying patients with severe Crohn's disease.

7719 ANTI-INFLAMMATORY AND IMMUNOSUPPRESSIVE TREATMENT OF NON-SPECIFIC INFLAMMATORY DISEASES OF THE INTESTINE. (Pol.) Bartnik, W.; Ruzyllo, E. (Klinika Gastroenterologii i Przemiany Materii CMKP, ul. Goszczynskiego 1, 02-616 Warsaw, Poland). *Pol. Tyg. Lek.* 31(47):2017-2020; 1976.

PANCREAS

7722 TIME-RELATED ENZYME CONCENTRATIONS IN DUODENAL ASPIRATES AFTER INGESTION OF A TEST MEAL. (Eng.) Ihse, I.; Lilja, P.; Evander, A.; Skude, G. (Dept. Surgery, Univ. Lund, S-221 85 Lund, Sweden). *Scand. J. Gastroenterol.* 12(5):629-635; 1977.

Enzyme concentration curves of trypsin, pancreatic isoamylase, phospholipase, and lipase in normal subjects and in patients with gastrointestinal disease are described. Enzyme concentrations were determined in duodenal aspirates during the first 2 hr of digestion of a test meal. In normal subjects, the concentration curves for all enzymes were biphasic, with an initial peak occurring after 10-20 min followed by a small increase during the second hour of enzyme collection. In patients with pancreatic cancer and chronic pancreatitis, the initial peak, if at all present, was not as pronounced as in normal individuals. In patients who had undergone a Billroth II resection, trypsin and phospholipase concentrations increased gradually. In these patients, as in the celiac disease patients, the lipase curve was different from that of trypsin and phospholipase. As lipase did not differ from the other enzymes in normal subjects, this phenomenon might reflect a nonparallel enzyme secretion in celiac disease and gastric resection patients as a consequence of altered stimulation. It may, however, also be related to the fact that lipase is secreted from the pancreas in an active form, while trypsin and phospholipase are secreted in a zymogen form. It is suggested that the enzyme concentration curves reflect pancreatic secretion. Because of the fairly considerable variation in enzyme concentration values from different individuals, it is concluded that the usual Lundh test (pool determinations) gives as good information as that obtained from complete concentration curves.

7723 FEEDBACK REGULATION OF PANCREATIC ENZYME SECRETION BY INTESTINAL TRYPSIN IN MAN.

(Eng.) Ihse, I.; Lilja, P.; Lundquist, I. (Dept. Surgery, Univ. Lund, S-221-85, Lund, Sweden). *Digestion* 15(4):303-308; 1977.

The effect of duodenal infusions of different substances on bile-pancreatic secretion was studied in a 70-yr-old man in whom a papilla of Vater tumor completely obstructed bile-pancreatic flow into the intestine. Pancreatic secretion in the subject was directed into the bile duct via a common channel that made it possible to sample the bile-pancreatic juice using a percutaneous transhepatic cholangiography catheter. Both bile-pancreatic secretion and the pancreatic output of amylase and lipase were markedly suppressed when the patient's own bile-pancreatic juice was returned to the duodenum at a rate of 1 mg/min. When an intraduodenal infusion of 1 mg/min of 0.05 M $NaHCO_3$ was given to the subject over a 30-min period, the amylase and lipase outputs were 3,989 and 4,986 U/15 min., resp., at the end of the 30-min period compared with amylase and lipase outputs of 2,015 and 3,503 U/15 min, resp., after a subsequent 30-min period when the patient's bile-pancreatic juice was returned to the duodenum. When trypsin inhibitor in combination with bile-pancreatic juice was returned to the duodenum over a subsequent 30-min period, the amylase and lipase outputs were increased to values of 5,053 and 9,766 U/15 min, resp. During a second series of experiments, an intraduodenal infusion of trypsin (1 mg trypsin/ml $NaHCO_3$) over a 30-min period decreased the flow and enzyme output from the pancreas, with the amylase and lipase outputs being 3,626 and 4,361 U/15 min, resp., compared with control values of 5,530 and 8,496 U/15 min, resp., after a 30-min infusion of 1 ml/min 0.05 M $NaHCO_3$. The results support the hypothesis that trypsin in the upper part of the intestine exerts a negative feedback regulation on pancreatic secretion in man.

7724 MASSIVE PANCREATIC ASCITES WITHOUT CARCINOMA: REPORT OF THREE CASES.

(Eng.) Hotz, J.; Goebell, H.; Herfarth, C.; Probst, M. (Medical Clinic, Univ. Essen, Hufelandstrasse 55, D-4300 Essen 1, W. Germany). *Digestion* 15(3):200-216; 1977.

The pathogenesis of benign pancreatic ascites is discussed on the basis of 3 personal cases and 94 literature cases. The common characteristics of the syndrome were chronic alcoholism (documented in 56 cases and suspected in 11), intermittent abdominal pain, nausea, vomiting, and considerable weight loss despite massive fluid accumulation. Markedly elevated protein and amylase levels in the ascitic fluid, hyperamylasemia, and hypoalbuminemia were the major diagnostic features. Two of the three new patients were chronic alcoholics. One showed subtotal hemorrhagic necrosis of the pancreas (diagnosed only at exploratory laparotomy), and the other had silent chronic pancreatitis with pseudocysts, possible slight leakage from a pseudocyst, as well as persistent thrombosis of the portal vein leading to portal hypertension with a distinct collateral circulation. The predominant cause of ascites was not apparent in this patient. The third patient, who was not alcoholic, had an acute attack of chronic pancreatitis with formation and rupture of a small pseudocyst of the main pancreatic duct. In this patient, the ascites disappeared after pancreaticojejunostomy. Endoscopic retrograde pancreatography was of diagnostic value in this patient.

7725 PROBLEMS IN THE DIAGNOSIS OF PANCREATIC CARCINOMA BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY.

(Eng.) Gregg, J. A.; Gramm, H. F.; Clouse, M. E. (New England Deaconess Hosp., 185 Pilgrim Rd., Boston, MA 02215). *Gastrointest. Radiol.* 2(1):61-65; 1977.

Diagnostic problems occurred in 5 of 55 patients undergoing endoscopic retrograde cholangiopancreatography who subsequently proved to have carcinoma of the pancreas; the case reports of these five patients and of two others in whom pancreatic duct abnormalities simulated carcinoma are presented. In one patient the pancreatic duct was normal, two had nonspecific ductal abnormalities, one had pancreas divisum, and one had ductal ectasia. Two patients with nonspecific changes on retrograde pancreatography had evidence of tumor on their retrograde cholangiogram. In the two patients with ductal obstruction simulating pancreatic cancer, one was due to compression by the thoracic spine, and the other was due to compression by inflammatory changes.

7726 PLEOMORPHIC CARCINOMA OF THE PANCREAS. AN ANALYSIS OF 15 CASES.

(Eng.) Tschang,

T. P.; Garza-Garza, R.; Kissane, J. M. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Cancer* 39(5):2114-2126; 1977.

In a retrospective histological study of 230 cases of pancreatic carcinoma, 15 pleomorphic carcinomas (PCP) were identified. PCP is characterized by a noncohesive, sarcoma-like growth pattern and mono- and multinucleated giant cells. Tumors were more likely to be located in the body and/or tail of the pancreas (9) than in the head or head and body of the pancreas (5). One tumor involved the entire pancreas. Size of the tumors varied from 3 to 15 cm with a median of 10 cm. The presenting symptoms of patients usually included pain, either of the abdomen or back, and (in two patients) in the chest. About half the patients experienced weight loss associated with anorexia, nausea, and vomiting. Only one patient had extensive surgery for the tumor (pancreaticoduodenectomy); this patient was the only long-term survivor (35 months). The other 14 patients died within 6 months of the onset of symptoms.

7727 PANCREATIC CYSTS IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY--A DIFFERENTIAL DIAGNOSTIC PROBLEM. (Ger.) Stuby, K.; Ammann, R.; Sulser, H.; Deyhle, P. (Departement fur Innere Medizin, Universitat Zurich, CH-8091 Ramistrasse 100, Zurich, Switzerland). *Z. Gastroenterol.* 14(7):689; 1976.

PANCREAS

Pancreatitis

7734 ANGIOGRAPHY OF MASSIVE HEMORRHAGE SECONDARY TO PANCREATIC DISEASE. (Eng.) Walter, J. F.; Chuang, V. P.; Bookstein, J. J.; Reuter, S. R.; Cho, K. J.; Pulmano, C. M. (Palo Alto Medical Clinic, 300 Homer Ave., Palo Alto, CA 94301). *Radiology* 124(2):337-342; 1977.

Angiographic findings from 20 patients with massive abdominal hemorrhage related to chronic pancreatitis, pancreatic neoplasms, and arteriovenous malformations are described. Abdominal hemorrhage in this group of patients drained most frequently into the gastrointestinal tract (18 patients) but also flowed through cutaneous drain sites and fistulas (3 patients) and once into a large pancreatic tumor. The most common angiographic observation in patients with bleeding secondary to pancreatitis was pseudoaneurysm formation (8 patients). The splenic artery was involved in six of these eight patients, the right gastroepiploic artery in one, and the transverse pancreatic artery in one patient. Frank contrast material extravasation, either into the gastrointestinal tract or i.p., was observed four times, with the angiographic appearance in these patients being no different than the usual findings in hemorrhage secondary to mucosal ulceration. Opacification of the entire pseudocyst was seen three times, and in each case the size of the pseudocyst at surgery corresponded to the structure observed angiographically. Pancreatic ductal filling, presumably due to erosion of an arterial wall directly communicating with the pancreatic duct, was seen along with flashing artery sign in one patient. Two patients with arteriovenous malformation had dilated, racemose feeding arteries and early dense filling of the draining veins. Three patients had pancreatic carcinoma and documented bleeding from gastroesophageal varices related to portal or splenic vein occlusion by the tumor.

7735 INFLAMMATION AND NECROSIS OF THE TRANSVERSE COLON SECONDARY TO PANCREATITIS.

(Eng.) Thompson, W. M.; Kelvin, F. M.; Rice, R. P. (Duke Univ. Medical Center, Durham, NC 27710). *Am. J. Roentgenol.* 128(6):943-948; 1977.

Radiographically demonstrable colon abnormalities secondary to acute pancreatitis were demonstrated in 12 of 220 patients (ages, 23-65 yr) with acute pancreatitis. Four patients showed dilatation localized to the transverse colon with no other colon abnormalities. Large inflammatory pancreatic masses displaced the transverse colon inferiorly in two patients and superiorly in a third patient. The inflammatory masses produced localized areas of spiculation of the mucosa at the site of displacement in one patient. Inflammation of the transverse colon, as evidenced by radiographic findings of narrowed lumen, irregularity of the colon wall, and/or a grossly abnormal haustral pattern, was observed in five patients. Stricture was radiographically demonstrated in one patient, and a large inflammatory mass in the tail of the pancreas extending around the splenic flexure was demonstrated at surgery. In one patient, a large pancreatic abscess eroded into the colon and produced a fistula from the pancreatic bed that communicated with the splenic flexure and the skin. Direct injection of the sinus demonstrated the fistula. One patient with initial radiographic findings of transverse colon inflammation subsequently developed necrosis of the transverse colon. A retrospective review of abdominal radiographs revealed an unchanged position of a dilated ahaustral splenic flexure over a 6-day period, suggesting the presence of colon necrosis. Transverse colon inflammation secondary to pancreatitis may be appreciated on plain abdominal radiographs; however, a contrast enema, which demonstrates that the abnormality is localized to the transverse colon and is not an ulcerative process, should help differentiate the transverse colon inflammation of pancreatitis from other entities. A water soluble contrast enema is recommended if there is any evidence of colon necrosis or fistula. The aggressive use of contrast enemas in patients with pancreatitis who are suspected of having a severe colon abnormality should speed the recognition of these complications.

7736 STEROIDS REVISITED. I. IS THERE A PLACE FOR STEROIDS IN THE TREATMENT OF PANCREATIC INFLAMMATION?

(Eng.) Dreiling, D. A.; Nacchiero, M.; Kaplan, M. H. (Mt. Sinai Sch. Med., City Univ. New York, 100th St. and Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 67(1):21-28; 1977.

The role of steroids in the treatment of pancreatic inflammation is discussed. Administration of prednisone (20-40 mg/day for 4-12 weeks) produced good to excellent results in 13/27 patients with subacute or persistent acute pancreatitis, 30/46 patients with intractable pain in pancreatic cancer, 8/8 patients with minipancreatitis following major pancreatic resection, 64/86 patients with intractable pain in chronic alcoholic pancreatitis, 6/12 patients with pancreatic ascites, and 2/2 patients with allergic pancreatitis. Average pancreatic secretory responses were studied in five fistula dogs undergoing secretin testing with or without acute steroid administration by injection or infusion. The values for pancreatic secretion rate (ml/5 min), bicarbonate concentration (mEq/l), bicarbonate output (mEq/5 min), protein concentration (mg/ml), and protein output (mg/5 min) were 3.78 ± 0.15 ($SP \leq 0.025$), 120.43 ± 3.94, 0.50 ± 0.04 ($SP \leq 0.010$), 11.95 ± 2.04 ($SP \leq 0.050$), and 52.25 ± 4.76, resp., with hydrocortisone (500-2,000 mg) and 4.29 ± 0.53 ($SP \leq 0.025$), 128.48 ± 2.97, 0.52 ± 0.04 ($SP \leq 0.010$), 11.95 ± 1.24 ($SP \leq 0.050$), and 45.51 ± 9.52 ($SP \leq 0.050$), resp., with prednisolone (80-160 mg), compared with control values of 5.54 ± 0.06, 119.41 ± 11.76, 0.69 ± 0.04, 11.04 ± 0.40, and 58.32 ± 10.87, resp. When two fistula dogs were given hydrocortisone (2 mg/kg/day) and/or prednisone (3.5 mg/kg/day) for 3 months, there was a reduction in basal flow, bicarbonate output, and protein output, but stimulated flow, bicarbonate output, and protein secretion were statistically increased. These findings are the end result of steroid-induced parenchymal augmentation, however, they do not explain the place of steroids in the treatment of pancreatic inflammation.

7737 SURGERY IN CHRONIC PANCREATITIS. A SURVEY OF A HOMOGENOUS SERIES OF FORTY CASES.

LIVER AND BILIARY TRACT

7741 THE USE OF ABDOMINAL CONTRAST TOMOGRAPHY IN LIVER DISEASE.

(Eng.) Dalla Palma, L.; Bacarini, L.; Bazzocchi, M. (Istituto di Radiologia dell'Universita, Ospedale Maggiore, 34125, Trieste, Italy). *Br. J. Radiol.* 50(595):483-488; 1977.

The diagnostic value of abdominal contrast tomography in liver diseases was assessed in 44 patients with liver disease and in 145 patients with a normal liver. A high dose of urographic contrast medium (66.8% sodium iothalamate, 150 ml) was used and infused rapidly in each patient. The method was useful in showing cysts, abscesses, and hepatic masses. Hypertrophy or atrophy were well visualized when the liver outline was deformed. The severity of the disease could be estimated by the degree of liver deformity and shrinkage. The technique was particularly valuable in the diagnosis of space occupying lesions with a poor blood supply; these showed areas of lucency. Hydatid cysts were identified by a sharp border with a regular wall surrounding a large space. Polycystic liver disease was also easily identified. Metastases appeared as homogeneous lucent areas with a sharp smooth margin if the lesion was encapsulated and with an irregular, sometimes blurred outline, if the lesion was infiltrating. Normal bile ducts were not seen, but became visible when they were dilated. The results show that rapid injection of a high dose of water soluble contrast medium results in good parenchymal opacification and that this technique is useful in the diagnosis of various liver diseases.

7742 THE RATE OF SYNTHESIS OF GLYCOSAMINOGLYCANS AND COLLAGEN BY FIBROBLASTS CULTURED FROM ADULT HUMAN LIVER BIOPSIES.

(Eng.) Galambos, J. T.; Hollingsworth, M. A.; Falek, A.; Warren, W. D. (Emory Univ. Sch. Medicine, Atlanta, GA 30303). *J. Clin. Invest.* 60(1):107-114; 1977.

Adult human liver biopsies from normal subjects and from patients with alcoholic hepatitis, chronic active hepatitis, fibrosis + alcoholic hepatitis (active cirrhosis), inactive cirrhosis, and drug hepatitis, were cultured to estimate the rate of synthesis of collagen (C) and glycosaminoglycans (GAG) by the cells. C synthesis was estimated in cultures from 58 livers by conversion of [^{14}C]proline to the [^{14}C]hydroxyproline of C; that of GAG was estimated in cultures from 57 livers by the incorporation of [^{3}H]acetate and $^{35}SO_4$ into the GAG. Pro-C synthesis was increased only in the alcoholic hepatitis cultures, both in the pulse ($p< 0.05$) and chase ($p<0.02$) media. Insoluble C synthesis (in disintegrations/min x 10^4/mg cell protein) was increased in cultures from chronic active hepatitis (28.0, $p<0.01$), fibrosis + alcoholic hepatitis (39.8 ± 7, $p<0.001$), and inactive cirrhosis (14.9 ± 4.1, $p<0.05$). The ratios of [^{14}C]hydroxyproline in pro-C:C were approximately 4:1 in alcoholic hepatitis and 2:1 in normal or drug hepatitis cultures, but they were 1:2 in firbosis + alcoholic hepatitis and inactive cirrhosis cultures. Essentially all radioactive GAG were soluble in the culture media. The predominant GAG were chondroitin -4 or -6-SO_4. GAG synthesis was increased only in fibrosis + alcoholic hepatitis (active cirrhosis) cultures, both in the pulse ($p<0.01$) and chase ($p<0.001$) media. There was no significant difference in C or GAG synthesis in paired cultures that contained 300 mg/dl ethanol or 3.75 mg/dl methyl prednisolone, compared to their respective controls. The results indicate an absence of immunologic mechanisms in hepatic fibrosis. It is suggested that hepatic fibrosis depends not only on the rate of hydrolysis of pro-C to C, but also on the composition of the ground substance that affects the rate and types of cross-linking of C.

7743 EVALUATION OF FLUORIMETRICALLY ESTIMATED SERUM BILE ACID IN LIVER DISEASE.

(Eng.) Osuga, T.; Mitamura, K.; Mashige, F.; Imai, K. (Univ. Tsukuba Sch. Medicine, Hongo 7-3-1, Bunkyo-ku, Tokyo 113, Japan). *Clin. Chim. Acta* 75(1):81-90; 1977.

The diagnostic efficacy of a fasting serum bile acid (SBA) assay was studied in 23 healthy subjects, 35 asymptomatic carriers of hepatitis B surface antigen (HBsAg), and 91 patients with various liver diseases (11 acute hepatitis, 37 chronic hepatitis, 33 posthepatitis or cryptogenic cirrhosis, 4 primary liver carcinoma, 4 primary biliary cirrhosis, and 2 constitutional nonconjugated hyperbilirubinemia). The assay consisted of incubating serum with a reagent composed of 0.1 ml 3α-hydroxysteroid dehydrogenase, 0.1 ml 0.5 μM NAD, 0.1 ml diaphorase, and 0.1 ml 200 μM reazurin followed by fluorimetric estimation of the amount of resorfin converted from reazurin. Fasting SBA levels in the 23 healthy controls ranged from 1.5 to 9.2 μM/l; the average SBA level in 35 asymptomatic HBsAg carriers was 7.2 ± 2.1 μM/l and all determinations were within the normal range. In the liver disease patients, SBA level was correlated with serum bilirubin content; LDH, GPT, and GOT levels; alkaline phosphatase content; and zinc sulfate test values. The SBA assay was a more sensitive index of impaired liver function than bilirubin or alkaline phosphatase content in 164 randomly selected liver disease patients. In addition, it permitted evaluation of the resolving phase of chronic liver disease.

7744 DYSFIBRINOGENEMIA ASSOCIATED WITH LIVER DISEASE. (Eng.) Palascak, J. E.; Martinez, J. (Jefferson Medical Coll., Thomas Jefferson Univ., Philadelphia, PA 19107). *J. Clin. Invest.* 60(1): 89-95; 1977.

To test the possibility that a functionally abnormal fibrinogen may exist in some patients with liver disease, the plasma and purified fibrinogens of five patients whose plasma thrombin times were prolonged at least 40% over normal controls were studied. No abnormalities were detected by immunoelectrophoresis of the plasmas of purified fibrinogens. The thrombin and reptilase times of the purified patient fibrinogens were prolonged from a normal value of 23.2 sec to 31.5-75.1 sec for the former and from 45.3 sec to 75.0->240.0 sec for the latter. Calcium ions (0.005 M) improved but did not completely correct these defects. Of the individual coagulation factors tested, the only abnormal findings common to all patients were a decreased level of factor X (0.39-0.56 μ/ml) and an increased level of factor VIII (1.64 to 4.99 U/ml). Increasing amounts of thrombin progressively shortened the clotting times of patient fibrinogens, but not to normal levels. Addition of equal amounts of patient fibrinogen to normal fibrinogen prolonged the thrombin time of normal protein. Thrombin-induced fibrinopeptide release was normal. Fibrin monomers prepared from patient plasmas and purified fibrinogens demonstrated impaired aggregation at low (0.12) and high (0.24) ionic strength. It is concluded that some patients with liver disease and prolonged plasma thrombin times have a dysfibrinogenemia functionally characterized by an abnormality of fibrin monomer polymerization.

7745 LIVER NEOPLASMS AND THE ORAL CONTRACEPTIVES. (Eng.) Keifer, W. S., Jr.; Scott, J. C. (1145 Broadway, Seattle, WA 98122). *Am. J. Obstet. Gynecol.* 128(4)448-454; 1977.

The relation between oral contraceptives and liver neoplasms was evaluated by reviewing the records of five Seattle hospitals during a 6.5-yr period and by reviewing the literature. Hospital records revealed nine cases of liver neoplasms (age range of patients, 15-50 yr); six of the nine women had used oral contraceptives. One unusual case is presented, and the remaining cases are summarized together with 87 cases found in the literature. A 28-yr-old woman who had used a combination of mestranol and ethynodiol diacetate for 11 months presented with infertility and the absence of menses for 6 months after the contraceptive was discontinued. Because of a palpable abdominal mass, abnormal liver enzyme studies, and radiographic findings, a laparotomy was carried out. A vascular tumor was found that was intimately adherent to the gallbladder and that arose from the undersurface of the anterior edge of the right lobe of the liver. Microscopically, it was diagnosed as a benign hepatic adenoma. The ovarian biopsies were normal, and the patient conceived 4 months after the tumor was excised. In the Seattle series and in the literature, the women with liver neoplasms and a history of oral contraceptive use were found to outnumber the women with liver neoplasms and no oral contraceptive use by more than two to one. In 44 cases associated with oral contraceptives where the parity was given, there were only 4 nulliparas. Mestranol was the most frequent estrogen used by nearly four to one. At least eight different progestins were encountered, and the most common compounds were norethindrone and norethynodrel. The duration of exposure to the contraceptives varied from 3-132 months in the literature and from 4-72 months in the Seattle group. All 96 patients underwent exploratory operations. Twelve patients died as a result of the tumor or complications of the operation. Close clinical surveillance with an awareness of this potentially fatal pathologic entity is essential in women who have ingested oral contraceptives.

7746 IMPAIRMENT OF DRUG METABOLISM IN PATIENTS WITH LIVER CANCER. (Eng.) Sotaniemi, E. A.; Pelkonen, R. O.; Mokka, R. E.; Huttunen, R.; Viljakainen, E. (Dept. Internal Medicine, Univ. Oulu, SF-90220 Oulu 22, Finland). *Eur. J. Clin. Invest.* 7(4):269-274; 1977.

Drug metabolizing capacity was investigated in six patients with primary hepatoma, three with primary hepatoma plus liver cirrhosis, and seven with metastatic liver disease by comparing *in vivo* (antipyrine disappearance rate from plasma) and *in vitro* (cytochrome P-450, benzpyrene hydroxylase, and 7-ethoxycoumarin O-deethylase activities in liver biospies) indices with those for tumor-free liver parenchyma and with biochemical liver function tests. Impairment of antipyrine metabolism was related to pathological changes in the liver. Significant differences in plasma antipyrine half-life ($p<0.001$) were seen between control subjects (8.9 ± 2.2 hr) and all cancer patients (18.6 ± 2.2 hr), patients with metastatic liver cancer (26.9 ± 10.1 hr), and patients with primary hepatoma plus cirrhosis (25.5 ± 2.7 hr). Patients with primary hepatoma only (occupying 20-80% of the liver volume) had normal antipyrine metabolism. A significant correlation between antipyrine half-life and serum albumin concentration was observed in patients with primary hepatoma only ($p<0.05$) and in all cancer patients ($p<0.001$), but not in patients with metastatic liver disease ($p>0.05$). The antipyrine half-life was not related to other liver function tests (bilirubin, aspartate, transferase, alkaline phosphatase, or thrombotest). Cytochrome P-450 content and benzpyrene hydroxylase and 7-ethoxycoumarin O-deethylase activities were low in and around the tumor of liver biopsies (ranges, 0.50-6.37 nmol/g, 8.6-383.3 pmol/g/min, and 50-1,100 fl/g/min, resp.) and high in the healthy liver parenchyma (ranges, 13.19-13.30 nmol/g, 566.7-1,158.2 pmol/g/min, and 2,930-6,400 fl/g/min, resp.). The dependence of the *in vitro* results on sampling site makes a comparison of these studies with plasma antipyrine half-life in the liver cancer patients impossible. The results demonstrate that in liver cancer patients, drug hydroxylating capacity depends on the ability of the tumor-free liver parenchyma to metabolize drugs. Hence, quantitative evaluation of liver changes together with tests measuring the synthesis capacity of the liver might be of significance when predicting drug metabolism in patients with hepatic malignancy.

7747 ANGIOGRAPHIC ASSESSMENT OF GROSS ANATOMY OF HEPATOCELLULAR CARCINOMA: COMPARISON OF CELIAC ANGIOGRAMS AND LIVER PATHOLOGY IN 100 CASES. (Eng.) Okuda, K.; Obata, H.; Jinnouchi, S.; Kubo, Y.; Nagasaki, Y.; Shimokawa, Y.; *et al.* Chiba Univ. Sch. Medicine, Chiba 280, Japan). *Radiology* 123(1):21-29; 1977.

The value of selective celiac and hepatic angiography in the diagnosis of liver tumors was studied in 100 patients with hepatocellular carcinoma (HCC). Since the clinical course and mode of treatment of HCC depend on the gross pathology, location, and spread of the tumor, the angiographic findings (hypervascularity, displacement of large arteries, arterioportal shunts, portal regurgitation) were recorded, and their frequency was correlated with the gross anatomical type. Anatomically, 8 patients had diffuse, 15 multinodular, 11 cirrhotic oligonodular, 15 encapsulated, 26 solitary expanding, 11 confluent, and 14 nodular massive tumors. A correct preoperative angiographic diagnosis was made in approximately 80% of the cases.

7748 ORAL FLUOROURACIL THERAPY OF HEPATOMA. (Eng.) Kennedy, P. S.; Lehane, D. E.; Smith, F. E.; Lane, M. (Baylor Coll. Medicine, Houston, TX 77030). *Cancer* 39(5):1930-1935; 1977.

5-Fluorouracil (5-FU, 15 mg/kg/week p.o.) was given to 12 consecutive patients with unresectable hepatoma, and the results were compared with those in 35 similar patients who were given other forms of chemotherapy (7) or symptomatic treatment only (28). Abdominal pain, weight loss, and an abdominal mass were the predominant presenting symptoms in all patients. Alkaline phosphatase, SGOT, bilirubin, albumin, and globulin levels were frequently abnormal. Six of the 12 p.o. 5-FU-treated patients showed an objective response. All six had at least 30% decrease in the subcostal liver span. One patient had normalization of liver function tests and a marked reduction of abdominal pain. Serial liver scans showed a 65% decrease in the size of a right lobe lesion in one patient. Four of the six responders had at least a 50% reduction in SGOT or alkaline phosphatase values, and a fifth had relief from recurrent hypoglycemia. Leukopenia, which required withholding 5-FU or reduction in dose, occurred in only two patients. The median survival time for the control and the p.o. 5-FU-treated nonresponder patients was 4 and 6 weeks, resp. The median survival for the six responders was 44 weeks ($p<0.001$).

7749 ABSORPTION OF INORGANIC IRON-($^{59}Fe^{2+}$) IN RELATION TO IRON STORES IN PANCREATIC EXOCRINE INSUFFICIENCY DUE TO CYSTIC FIBROSIS. (Eng.) Heinrich, H. C.; Bender-Gotze, Ch.; Gabbe, E. E.; Bartels, H.; Oppitz, K. H. (Univ. Hosp. Eppendorf, Univ. Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Klin. Wochenschr.* 55(12):587-593; 1977.

Inorganic Fe (^{59}Fe) absorption was studied in 22 children with pancreatic exocrine insufficiency due to cystic fibrosis, and it was related to the amount of stainable diffuse cytoplasmic nonheme storage Fe in the bone marrow macrophages of these children. When Fe storage was within the normal range, the children absorbed 21 ± 9.3% (range, 9.6-38%) of a diagnostic $^{59}Fe^{2+}$ dose (0.56 mg) administered p.o.; this absorption was similar to that observed in control children with normal Fe stores (23 ± 8.7%; range 9-45%). Depletion of Fe stores increased ^{59}Fe absorption to 62 ± 19% (range, 43-95%) in children with cystic fibrosis and to 73 ± 18% (range, 45-100%) in control children. The interruption or continuation of pancreatin maintenance therapy and the simultaneous administration of 1-1.5 g pancreatin did not influence $^{59}Fe^{2+}$ absorption in cystic fibrosis. Since children with cystic fibrosis absorb inorganic and food Fe like normal children (according to the amount of available storage Fe) and since pancreatin does not influence Fe absorption, it is highly improbable that children with cystic fibrosis will develop hemosiderosis, even without pancreatin maintenance therapy.

7750 REDUCED MICROBIAL TRANSFORMATION OF BILE ACIDS IN CYSTIC FIBROSIS. (Eng.) Lefebvre, D.; Ratelle, S.; Chartrand, L.; Roy, C. C. (Hopital Sainte-Justine, Univ. Montreal, 3175, chemin Sainte-Catherine, Montreal H3T 1C5, Quebec, Canada). *Experientia* 33(5):616-618; 1977.

The capacity of fecal flora from 13 patients with cystic fibrosis (CF) to transform bile acids was compared with that from 9 normal children. Chromatography revealed that the microbial transformation of bile acids by incubates of stool homogenates from the CF patients were decreased. A larger percentage of radioactivity was recovered from the spot corresponding to taurocholic acid in the nine CF patients with pancreatic insufficiency (3.1 ± 1.1%) than in controls (0.5 ± 0.07%, $p<0.025$) or in the four CF patients with normal pancreatic function (1.0 ± 0.5%, $p<0.05$). In experiments carried out with labeled glycocholic acid, there was no difference between the three groups. The taurine amide bond was much more vulnerable to hydrolysis than the glycine bond for the three groups. The results of incubations carried out with the cholic and chenodeoxycholic acids showed a significant decrease of dehydroxylation to deoxycholic acid and lithocholic acid in the CF patients with pancreatic dysfunction in comparison with controls ($p<0.005$ for both deoxycholic and lithocholic acids). In addition, the capacity of the stools of the four CF patients with normal pancreatic function for the dehydroxylation of chenodeoxycholic acid to lithocholic acid was lower than that of control stools ($p<0.025$).

7751 PLASMA SHORT-CHAIN FATTY ACIDS IN FULMINANT HEPATIC FAILURE.

(Eng.) Lai, J. C. K.; Silk, D. B. A.; Williams, R. (King's Coll. Hosp., Denmark Hill, London SE5, England). *Clin. Chim. Acta* 78(2):305-310; 1977.

Blood levels of short-chain fatty acids (SCFA) were measured by gas-liquid chromatography in six patients with fulminate hepatic failure (FHF). The patients were all in a grade IV coma when they were admitted (5 had taken an overdose of acetaminophen, 1 had a presumed hepatitis A viral infection), and four patients had evidence of renal failure during the course of their illness. Blood samples were taken from the time of admission to death or when conscious levels improved to grade II or III coma. Patients were treated with full supportive measures, including lactulose, magnesium, vitamins, blood transfusions, and hemodialysis. The initial SCFA levels were similar in patients who subsequently died and in those who survived. Furthermore, the SCFA levels in patients in a deep coma just before death were normal and did not differ from levels in survivors with improved conscious grades. It is concluded that a primary role for SCFA in the pathogenesis of coma in FHF patients appears unlikely.

7752 DISPOSITION KINETICS OF SPIRONOLACTONE IN HEPATIC FAILURE AFTER SINGLE DOSES AND PROLONGED TREATMENT.

(Eng.) Abshagen, U.; Rennekamp, H.; Luszpinski, G. (Med. Klinik und Poliklinik, Klinikum Steglitz, Hindenburgdamm 30, D-1000 Berlin 45, W. Germany). *Eur. J. Clin. Pharmacol.* 11(3): 169-176; 1977.

Spironolactone (SL) pharmacokinetics was studied in six men with histologically verified liver lesions (3 cirrhosis with ascites, 1 cirrhosis without ascites, and 2 acute alcoholic hepatitis with ascites). The treatment schedule was divided in two parts: the first consisted of Aldactone (Ald, 7 mg/kg p.o.) plus ^{3}H-SL (100 μCi p.o.), followed by a 6-day examination of the drug kinetics in the plasma and urine. The second part consisted of Ald (7 mg/kg/day for 12 consecutive days) plus varying doses of saliuretics (furosemide), followed by a second dose of ^{3}H-SL, and the kinetics of the drug were reassessed during the next 6 days. A single dose of Ald did not alter the pattern of fluorigenic metabolites in the plasma; urinary excretion of total radioactivity (47.5%) was also similar to that in healthy controls (52.9%). The 12-day treatment with Ald accelerated the elimination of radioactivity from the plasma markedly and increased urinary excretion of labeled metabolites in four of six patients. The relative decrease in the elimination of radioactivity from the two other patients was probably due to iatrogenic dehydration caused by an overdose of diuretics.

7753 TREATMENT OF PORPHYRIA CUTANEA TARDA BY PHLEBOTOMY.

(Eng.) Ippen, H. (Kliniken der Universitat Gottingen, Hautklinik und Poliklinik, 34 Gottingen, W. Germany). *Semin. Hematol.* 14(2):254-259; 1977.

Three hundred fifty-one patients with porphyria cutanea tarda (PCT) were treated by phlebotomy (weekly withdrawal of 500 ml blood) and then observed for 10-17 yr. Most of the patients (97%) tolerated the phlebotomies and achieved improvement of the cutaneous symptoms and normalization of the urinary porphyrin content (but not of its pathological distribution pattern). One-third of the patients had no relapse for at least 6 yr. Even patients who continued to consume large amounts of alcohol stayed in remission for this period. Another one-third of the patients experienced biochemical relapses of varying severity within 2-4 yr after treatment. The last third consisted of (1) patients in whom therapy was stopped by the patient because of disappearance of cutaneous symptoms or completion of treatment and (2) patients lost to follow-up. Some were reexamined later and assigned to one of the other two groups. In all patients, the liver profile (transaminase level and BSP retention) and hypergammaglobulinemia generally returned to normal. Hemoglobin values rose above 16 g/100 ml 3 months prior to elevation of the urinary porphyrin values. Serum iron levels, which normalized 2-3 months after phlebotomy, rose to pathologic values 3-6 months after completion of treatment. Diabetes mellitus, which occurred in approximately one-fifth of the patients, persisted. The hypertrichosis in some female patients reappeared prior to repeated elevation of urinary porphyrin. Diminished porphyrin content, reduction of siderosis, and decreased fatty degeneration were observed in three patients who died from unrelated causes. In summary, the treatment of PCT with phlebotamies is effective and leads to the disappearance of cutaneous symptoms, amelioration of increased urinary excretion of porphyrins, and improvement of most other abnormalities except diabetes.

7754 PORPHYRIN METABOLISM IN PORPHYRIA CUTANEA TARDA.

(Eng.) Elder, G. H. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff CF4 4XN, Wales). *Semin. Hematol.* 14(2):227-242; 1977.

In this review, the abnormalities of porphyrin storage and excretion that characterize porphyria cutanea tarda (PCT) and their relation to the enzymes of heme biosynthesis in the liver are discussed. The abnormalities of porphyrin metabolism in PCT can be related to a single primary enzyme defect--a decrease in hepatic urogen decarboxylase activity. The situations in which PCT arises are so varied that the cause of the decrease in urogen decarboxylase is not likely to be the same in all cases. It is concluded that increased δ-aminolevulinate formation, resulting from alcohol, iron overload, or estrogens or perhaps from synergism between different causative agents, is the main determinant of the ability of these agents to produce PCT in susceptible individuals.

7755 HEPATIC SIDEROSIS AND PORPHYRIA CUTANEA TARDA: RELATION OF IRON EXCESS TO THE METABOLIC DEFECT. (Eng.) Felsher, B. F.; Kushner, J. P. (Veterans Admin. Hosp., 5901 E. 7th St., Long Beach, CA 90822). *Semin. Hematol.* 14(2):243-251; 1977.

Clinical evidence in support of a role for Fe in the pathogenesis of porphyria cutanea tarda (PCT) and the biochemical alterations that result from excess Fe are reviewed. Hepatocellular and Kupffer cell siderosis with significant uroporphyrinuria is the most common (≥80%) abnormality of Fe metabolism in PCT patients. Although reduction of the Fe stores causes a biochemical remission, the pathogenetic significance of the hepatic Fe content in PCT has not been clearly defined. Fe might play only a permissive role in porphyrin metabolism. Fe augments the induction of hepatic δ-aminolevulinic acid synthetase (ALA-S) activity and increases porphyrin synthesis in animals. Any consideration of the role of Fe in the pathogenesis of PCT must take into account the clinical observation than an Fe overload alone does not induce the disease. This suggests that there is an underlying biochemical defect in PCT patients resulting in an unusual sensitivity of these patients to the effects of Fe and perhaps other agents, e.g., alcohol and estrogens. That such a defect may be genetically determined is supported by the finding of decreased urogen decarboxylase activity in the RBC and liver of PCT patients. It is concluded that two primary factors are essential for the full biochemical expression of PCT: an inherited enzyme defect, decreased urogen decarboxylase activity, and an acquired factor, hepatic siderosis.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

7771 BREAST MILK JAUNDICE: AN IN VITRO STUDY OF THE EFFECT OF FREE FATTY ACIDS ON THE BILIRUBIN-SERUM ALBUMIN COMPLEX. (Eng.) Yong, F. C.; Cheah, S. S. (Dept. Chemistry, State Univ. New York, 1400 Washington Ave., Albany, NY 12222). *Res. Commun. Chem. Pathol. Pharmacol.* 17(4):679-688; 1977.

The quantity of fatty acids required to displace bilirubin from its bovine serum albumin (fraction V) binding sites was studied to ascertain the possible effect played by free fatty acids on the development of the breast milk jaundice syndrome. The concentrations of bilirubin and bovine serum albumin were measured spectrophotometrically. Bilirubin binding to albumin was followed by measuring the shift in absorption maximum, 437 nm to 468 nm, as well as by thin-layer chromatography (TLC). Oleic acid concentrations <1.2 mg%, when added to the bilirubin-albumin conjugate, increased the absorption maximum at 468 nm with a concomitant decrease in absorbance close to 410 nm. Oleic acid concentrations >1.1 mg% decreased the absorption maximum at 468 nm and shifted the maximum toward shorter wavelengths while increasing the absorbance at 410 nm. Binding constants calculated for the bilirubin-albumin complex were $K_1=4.6 \times 10^5$ M^{-1} and $K_2=1.3 \times 10^4$ M^{-1}, which are similar to values reported in the literature. A concentration of oleic acid of greater than 1.1 mg% was required to initiate bilirubin displacement from the bovine-albumin complex, and a similar result was obtained with stearic, palmitic, and linoleic acids. TLC experiments showed that oleic acid (9.9 mg%) released about 50% of the bilirubin from the complex of bilirubin-albumin (1:2 molar ratio). A decreased quantity of oleic acid (4.9 mg%) also released a large amount of bilirubin when added to a solution containing a lower bilirubin-albumin molar ratio (1:1). Since oleic and palmitic acid concentrations are high in breast milk, an infant may ingest enough fatty acid to influence bilirubin binding; this effect coupled with the rate of heme breakdown and the activation of liver glucuronyl transferase may accentuate breast milk jaundice.

7772 A MULTIFACTORIAL SURVEY OF NEONATAL JAUNDICE. (Eng.) Jeffares, M. J. (British Military Hosp., Rinteln, BFPO 29, England). *Br. J. Obstet. Gynaecol.* 84(6):452-455; 1977.

The importance of the induction of labor using oxytocin and of other factors in the development of neonatal jaundice was analyzed in a retrospective survey of 981 deliveries. Of these infants, 84 developed hyperbilirubinemia (total serum bilirubin >222 μM). There were no statistically significant differences between the normal and the hyperbilirubinemic infants with regard to maternal age, parity, length of gestation, or birth weight. In 22 hyperbilirubinemic infants, labor was spontaneous, without the administration of oxytocin. Low, medium, or high doses of oxytocin (i.e., 2-16, 16-64, and >64 mU/min) were administered for the augmentation or induction of labor in 18, 31, and 31 of the remaining cases, resp. The incidence of jaundice was significantly higher ($p<0.001$) in association with the use of medium or high doses of oxytocin. When augmented spontaneous labors and induced labors were compared separately with nonaugmented spontaneous labor, only induced labors showed a significant excess of jaundiced babies, which suggests that induction itself might be a contributory factor in the development of neonatal jaundice. Cigarette smoking, Apgar score, vitamin K analogues, and intrauterine growth retardation were not significantly related to neonatal jaundice. The results suggest that high doses of oxytocin should be used with caution.

7773 THERAPEUTIC EFFICACY OF URIDINE DIPHOSPHOGLUCOSE (UDPG) IN NONHEMOLYTIC FAMILIAL JAUNDICE: METABOLIC STUDY IN A PATIENT WITH DUBIN-JOHNSON SYNDROME. PART II.

(Ita.) Cortellazzo, S.; Orlando, R.; Ortolani, C.; Dal Brun, G.; Okolicsanyi, L. (Istituto di Clinica Medica Generale I, Universita di Padova, Padua, Italy). *Clin. Ter.* 77(5):459-472; 1976.

The pathophysiology of chronic idiopathic jaundice (Dubin-Johnson syndrome) was analyzed in a 25-yr-old man presenting with this disease. Liver function studies included bilirubin turnover and transport, BSP excretion, indocyanine green clearance, cholecystography, and percutaneous cholangiography. Total functional liver mass was evaluated by galactose excretion and drug metabolizing capacity by antipyrine clearance. The patient was given 80 mg/day of parenteral uridine diphosphoglucose (UDGP) for 14 days, followed by a second course 7 days later of 50 mg/day for 30 days. To investigate the combined therapeutic effect of UDPG and sodium phenobarbital, therapy was extended 30 additional days with 50 mg/day of UDPG i.m. and 150 mg/day of sodium phenobarbital p.o. UDPG had a favorable effect upon bilirubin metabolism, with a reduction of bilirubinemia and a net improvement in pigment kinetics. There was also a net increase in antipyrine clearance, and it was possible to visualize the gallbladder, which could not be seen in pretreatment radiographs. Combined UDPG-phenobarbital treatment produced a further reduction in bilirubinemina and an amelioration of other clinical findings.

7774 THE DUBIN JOHNSON SYNDROME AND PREGNANCY.

(Eng.) Seligsohn, U.; Shani, M. (Chaim Sheba Medical Center, Tel Aviv Univ., Tel Hashomer, Israel). *Acta Hepatogastroenterol.* 24(3):167-169; 1977.

Fetal mortality was studied in 18 patients with the Dubin-Johnson Syndrome (DJS). A fetal mortality of 16% was observed in 75 pregnancies in the 18 DJS patients. This value was not significantly different from the 10% mortality observed in 81 pregnancies in 15 matched controls. Jaundice was accentuated in 54% of pregnancies in the DJS patients and its time of onset was variable. In six instances, jaundice was observed only following delivery. These data do not support previous studies that have suggested that the frequency of fetal mortality in DJS is high.

7775 PRESENT STATUS OF THE CLINICAL, NOSOGRAPHICAL, PHYSIOPATHOLOGICAL, AND THERAPEUTIC FEATURES OF GILBERT'S ICTERUS. THERAPEUTIC ACTION OF ENZYMIC INDUCTORS WITH RESPECT TO UNCONJUGATED BILIRUBIN ICTERUS.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7777 CLINICAL AND EXPERIMENTAL ASPECTS OF PARACETAMOL HEPATOTOXICITY.

(Eng.) Williams, R.; Davis, M. (King's Coll. Hosp. Medical Sch., London, England). *Acta Pharmacol. Toxicol.* 41(Suppl. 2):282-298; 1977.

The pattern of urinary conjugates of paracetamol in normal volunteers after therapeutic doses of the drug and patients admitted to hospital early after suicidal attempts was studied because the number of deaths due to self-poisoning with this drug has increased. In normal volunteers, 90% of a therapeutic dose of paracetamol was metabolized by hepatic enzymes and excreted into urine as glucuronide and sulfate conjugates, with small amounts of cysteine and mercapturic acid conjugates, within 12 to 24 hr of ingestion. As the administered dose of paracetamol was increased, marked changes were observed in the ratios of the conjugates, with less of the drug appearing as the glucuronide and sulfate conjugates and a higher proportion as the cysteine and mercapturic acid conjugates in the urine. The quantity of paracetamol ($[^{14}C]$ring-labeled) metabolite bound within the liver of rats (54 ± 5.4-358 ± 37.0 nmol/g wet liver), which correlates with the degree of hepatic necroses (1.3 ± 1.5-39.3 ± 4.4%), increases in proportion to the rate of urinary excretion of cysteine and mercapturic acid conjugates (0.08 ± 0.02-0.60 ± 0.05 nmol/24 hr) following varying doses of the drug (0.82-5.80 nmol/rat). Alpha mercapto propionyl glycine (α MPG) appeared to prevent the deleterious effects of the bound reactive metabolite of paracetamol, although the quantity of covalently bound paracetamol metabolite in the livers of rats receiving α MPG was not significantly less than that observed in animals not receiving this compound. It is suggested that this protective action would normally be exerted by hepatic reduced glutathione and that α MPG substitutes for the reduced glutathione in this function. It is concluded that neither depletion of hepatocellular glutathione nor covalent binding of the reactive paracetamol metabolite produce hepatocellular necrosis if present singly, but if they coexist, then hepatic damage ensues.

7778 FATAL HEPATIC NECROSIS AFTER HALOTHANE ANESTHESIA IN A BOY WITH JUVENILE RHEUMATOID ARTHRITIS: A CASE REPORT. (Eng.) Campbell, R. L.; Small, E. W.; Lesesne, H. R.; Levin, K. J.; Moore, W. H. (North Carolina Memorial Hosp., NC). *Anesth. Analg. (Cleve.)* 56(4):589-593; 1977.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

7781 HEPATITIS A IN MILITARY FAMILIES: ANATOMY OF AN EPIDEMIC. (Eng.) Nowosiwsky, T.; Irwin, G. R., Jr.; Ferguson, J. A.; Randall, D. H. (Walter Reed Army Inst. Res., Washington, DC 20012). *Milit. Med.* 142(9):693-695; 1977.

The transmission and control of an outbreak of hepatitis A infection in a group of military families were studied. The outbreak involved 14 persons. It was shown that the outbreak was person-propagated, and that it occurred by the oral route. The index case was a woman who visited friends almost daily and had given two parties that the patients had attended. The report includes a case of aplastic anemia that occurred following the outbreak.

7782 VIRAL HEPATITIS AMONG PRACTISING DENTISTS. (Eng.) Nicholas, N. K. (Sch. Dental Nurses, Auckland, New Zealand). *N.Z. Med. J.* 85(588):413-416; 1977.

The incidence of viral hepatitis was assessed among a group of 242 Auckland dentists. A questionnaire survey revealed 47 episodes of viral hepatitis in 45 dentists; 7 were reported before the commencement of treating patients as dental students, 5 while treating patients as dental students, and 34 after graduation and while engaged in clinical practice. Twenty-two episodes were diagnosed as infectious hepatitis, 5 were diagnosed as serum hepatitis, and the remaining 13 were not differentiated. A literature review reveals that Auckland practicing dentists show a markedly higher hepatitis infection rate than similar groups of American dentists. The incidence of viral hepatitis among practicing dentists in Auckland appears to be rising. This study supports the view that dentists are at higher risk of contracting viral hepatitis than the general population because of the nature of their occupation.

7783 ROLE OF SEXUAL AND NON-SEXUAL PRACTICES IN THE TRANSMISSION OF HEPATITIS B. (Eng.) Lim, K. S.; Wong, V. T.; Fulford, K. W. M.; Catterall, R. D.; Briggs, M.; Dane, D. S. (Middlesex Hosp., London W1N 8AA, England). *Br. J. Vener. Dis.* 53(3):190-192; 1977.

Medical, social, and sexual histories were taken from 198 men attending a department for sexually transmitted diseases. Their blood was tested for hepatitis B surface antigen (HBsAg) and its antibody (anti-HBs) and also for syphilis and liver function. Of the 30 homosexual and 46 bisexual patients, 10 and 17, resp., were HBsAg- or anti-HBs-positive; in contrast, only 6 of 117 heterosexual patients were anti-HBs-positive. Hepatitis B appeared to be transmitted sexually rather than by other means, but it was not possible to link its transmission with any particular homosexual practice. However, risk of infection increased considerably with the number of sexual partners and nearly half of those with more than 40 sexual partners had been infected.

7784 AUSTRALIA ANTIGEN AND THE BIOLOGY OF HEPATITIS B.

(Eng.) Blumberg, B. S. (Inst. Cancer Res., Fox Chase Center, Philadelphia, PA 19111). *Science* 197(4298):17-25; 1977.

Events leading to the discovery of the Australia antigen, or the hepatitis B surface antigen (HBsAg), are described. HBsAg is very stable and can be removed from Dane particles by the action of detergents to reveal the core, which has its own antigen (HBcAg). Antibodies to both these antigens (anti-HBs and anti-HBc) can be detected in human blood by immunological techniques. Efforts to produce an effective vaccine against viral hepatitis are in progress. The variations in response to infection with hepatitis B, familial distributions of responses to this infection, sex of the offspring and the fertility of infected parents, primary hepatic carcinoma, transmission by insects, hepatitis B as a polymorphism, and bioethics and the carrier state of hepatitis are the other topics discussed. With the availability of serologic and environmental tests for hepatitis B, it is now possible to begin the design of control measures for this disease. If hepatitis B vaccine is found to be effective, it may also be of value in preventing the development of the carrier state of the disease.

7785 FREQUENCY OF HEPATITIS B SURFACE ANTIBODY (ANTI-HBs) IN VARIOUS CANADIAN POPULATIONS AS MEASURED BY MODIFIED SOLID-PHASE RADIOIMMUNOASSAY.

(Eng.) Bishai, F. R.; MacMillan, S.; Dempster, G.; Rhodes, A. J.; Spence, L.; Wrobel, D. M. (Ontario Ministry Health, Box 9000, Terminal A, Toronto, Ontario, Canada M5W IR5). *Can. J. Microbiol.* 23(1): 92-99; 1977.

A sensitive, short-incubation, solid-phase radioimmunoassay (RIA) for detecting antibody to hepatitis B surface antigen (anti-HBs) is described. The technique consists of coating polystyrene tubes with sera positive for HBsAg, labeling HBsAg with ^{125}I, 4-hr incubation of the test sample with ^{125}I-HBsAg, and assessing the remaining radioactivity by a gamma counter or a liquid scintillation spectrometer. Positive sera were confirmed by a passive hemagglutination (PHA) and counterelectrophoresis (CEP) assay. There was 97.7% agreement between the RIA and PHA assays. From 1973 to 1975, this RIA was used to detect anti-HBs in HBsAg-negative specimens from suspected hepatitis patients and laboratory staff members. Of 5,869 specimens tested, 647 contained anti-HBs. The incidence of anti-HBs showed significant variability in different populations. According to a statistical analysis, the populations could be classified into three categories: (1) students and administrative staff, in whom the incidence of anti-HBs was 0% (low-risk group); (2) microbiology, pathology, and histology technologists, and the staff from a renal dialysis unit in a general hospital, in whom the incidence of anti-HBs ranged from 9% to 16% (overall frequency, 12.8%; intermediate-risk group); and (3) a group consisting of biochemistry and hematology technologists and pathologists, in whom the incidence of anti-HBs ranged from 26.6% to 44.3% (overall frequency, 39.5%; high-risk group).

7786 HEPATITIS B IN SUBJECTS TREATED WITH A DRUG CONTAINING IMMUNOGLOBULINS.

(Eng.) Petrilli, F. L.; Crovari, P.; De Flora, S. (Inst. Hygiene, Univ. Genoa, Via Pastore 1, 16132 Genoa, Italy). *J. Infect. Dis.* 135(2):252-257; 1977.

In late 1974 and early 1975, >100 cases of viral hepatitis occurred in Italians who had received s.c. injections of the drug Trilergan, which was prescribed for the treatment of allergies. The drug contains, in one 1-ml dose, 12 mg human immunoglobulins, 0.15 μg histamine hydrochloride, 0.15 μg serotonin, 0.1 mg sodium merthiolate, 9 mg NaCl, and 20 mg mannitol. Epidemiologic and laboratory investigations provided evidence that the original immunoglobulins, all drug lots in the series containing these immunoglobulins, and sera from 28/30 patients were all positive for hepatitis B surface antigen (HBsAg) subtype *adw*, which is relatively rare in Italy. Sera collected 8.0 and 5.5 months, resp., after the onset of symptoms from the two patients who were not HBsAg-positive were positive for anti-HBs (*adw* specificity). The sera of three healthy, viral hepatitis-free subjects who had received the HBsAg-positive series drug had circulating anti-HBs. The clinical course of the disease was consistent with typical forms of icteric hepatitis in all patients examined. The average incubation period was 111-143 days, and there was an inverse relationship between the number of doses administered and the length of the incubation period. The possibility that immunoglobulins can transmit hepatitis B raises a number of problems concerning the control and use of these blood products.

7787 ABO BLOOD GROUPS AND HBsAG SUBTYPES AND TITERS IN HEALTHY CARRIERS.

(Eng.) Babes, V. T.; Steiner, N.; Lenkei, R.; Buzernescu, G. (Stefan S. Nicolau Inst. Virology, Bucharest 4, Sos. Mihai Bravu 283, Rumania R-74339). *Vox Sang.* 33(4):252-256; 1977.

The distribution of ABO blood groups in 457 healthy hepatitis B surface antigen (HBsAg) carriers was investigated. HBsAg was detected by counterelectrophoresis; the HBsAg subtype was identified by immunodiffusion in 317 cases. The *ay* subtype was the most common subtype, with an *ay/ad* ratio of 82/18. The percentages of blood groups, O, A, B, and AB among the 457 antigen carriers were 31.9, 43.9, 13.9, and 10.3, resp., while those of a normal population were 42, 43, 11, and 4, resp., There were significant differences in the incidence of HBsAg/*ad* according to blood group; the *ad* subtype was detected in only 17% of the type O sera, while this incidence in type AB sera was 33%. The results suggest the possibility that susceptibility to HBsAg is regulated by a genetic mechanism.

7788 HBeAg AND ANTI-HBe IN ACUTE HEPATITIS PATIENTS AND HBsAg CARRIERS.

(Ita.) Zanetti, A. R. (Istituto di Virologia, Universita di Milano, Via Pascal 38, 20133 Milan, Italy). *Boll. Ist. Sieroter. Milan.* 56(1):76-78; 1977.

Serial samples of serum from 44 patients with acute hepatitis B were examined by immunodiffusion and radioimmunoassay to identify hepatitis B antigen (HBeAg) and its antibody (anti-HBe). HBeAg was detected in the serum of 5 patients, anti-HBe in 12. Two patterns of events emerged: (1) HBeAg was found only in samples collected during the early acute phase of the illness, but anti-HBe could not be detected at any time; (2) HBeAg was not found during the acute phase, but anti-HBe was detected 4 to 6 weeks after the onset of clinical jaundice, when hepatitis B surface antigen (HBsAg) was still present but before the appearance of anti-HBs. HBeAg was persistently found in the sera of 12/16 chronic renal failure patients that were long-term carriers of HBsAg and anti-HBe was found in 2. Anti-HBe was detected in 33/50 asymptomatic HBsAg carriers, HBeAg in only 1. HBeAg and anti-HBe were not detected in any of the 15 patients with HBsAg-negative acute or fulminating hepatitis or in any of 20 healthy individuals that had no serological evidence of past or current hepatitis B virus (HBV) infection (negative controls). The data confirm a specific association between the determinant and HBV, and they imply a correlation of HBeAg persistence with HBV infectivity and of anti-HBe with asymptomatic carriage of surface antigen.

7789 EARLY DIAGNOSIS OF HEPATITIS B BY DANE PARTICLE ASSOCIATED DNA POLYMERASE ASSAY.

(Eng.) Cappel, R.; de Cuyper, F.; van Beers, D.; Toppet, M.; Cadranel, S. (Dept. Virology, Inst. Pasteur du Brabant, Brussels, Belgium). *J. Gen. Virol.* 36(1):217-220; 1977.

One hundred and seventy-eight subjects exposed to hepatitis B and 120 hemodialyzed patients were investigated for the presence of hepatitis B surface antigen (HBsAg), e antigen, and DNA polymerase as well as for antibody to HBsAg (anti-HBs). A positive correlation between the presence of e antigen and of DNA polymerase was observed in 83% of the patients on hemodialysis who developed hepatitis B but in only 9% of the 178 other patients who developed the same disease. The results suggest that the DNA polymerase assay may enable an earlier diagnosis of hepatitis B than does radioimmunoassay for HBsAg; in addition, DNA polymerase might be present in the blood in the absence of HBsAg in cases of confirmed hepatitis B.

7790 SERUM GLYCOPROTEINS IN THE LIVER DISEASES. III. DESIALYLATED GLYCOPROTEINS IN THE ACUTE HEPATITIS.

(Eng.) Arima, T.; Motoyama, Y.; Yamamoto, T.; Nagata, K.; Kondo, T. (Okayama Univ. Medical Sch., Okayama, 700, Japan). *Gastroenterol. Jpn.* 12(2):39-42; 1977.

Circulated desialylated glycoprotein (DGP) levels were determined in 20 normal subjects, 7 patients with acute hepatitis (during the peak of illness), 11 patients recovering from acute hepatitis, and in 4 patients with fulminating hepatitis. The levels were followed throughout the course of acute hepatitis in one patient and during fulminant hepatitis in another patient. In the former patient, the serum DGP level was elevated on the first observation; it increased thereafter, reaching a peak on the eighth day of hospitalization. The DGP level returned to normal before the SGPT and serum bilirubin levels did. In the patient with fulminating hepatitis, the DGP level was increased on the initial observation; it increased thereafter, and the patient died on the fourth hospital day. The mean DGP levels in the normal subjects, the patients with acute hepatitis, and the patients with fulminating hepatitis were 3.24 ± 0.91, 5.81 ± 0.99, and 12.6 ± 2.92 ng/10 μl, resp.; the levels were increased significantly ($p<0.001$) in acute and fulminating hepatitis, in comparison with controls. A significant difference ($p<0.001$) in the level between acute hepatitis at the peak of illness and fulminating hepatitis at the peak SGPT activity was also observed. The mean DGP level in 58 sera obtained from 11 patients recovering from acute hepatitis was within the normal range. The results suggest that DGP elevation during the course of fulminant hepatitis represents irreversible parenchymal cell damage.

7791 SERUM ISOENZYMES IN PATIENTS WITH SUBSIDING VIRAL HEPATITIS FOLLOWING BICYCLE ERGOMETER LOAD.

(Ger.) Sieber, H.; Weigl, E.; Bach, H. (Zentrallaboratorium der Kreispoliklinik, Friedrich-Engels-Strasse 39, DDR-122 Eisenhuttenstadt, E. Germany). *Dtsch. Gesundheitsw.* 32(30):1419-1423; 1977.

The isozyme patterns of total, mitochondrial, and cytoplasmic SGOT (SGOT-T, SGOT-M, and SGOT-C, resp.) and total, muscle, and liver serum aldolase (ALD-T, ALD-M, and ALD-L) were studied in 40 patients with subsiding viral hepatitis 45 min and 22 hr after a bicycle ergometer load test. The values obtained were compared to pretest values (100%). The patients were subdivided into three groups: (1) 15 were tested

5-9 weeks after the onset of hepatitis, (2) 15 were tested 10-14 weeks after onset, and (3) 10 were tested 15-24 weeks after onset. The load test (2 x 10 min, 50-100 W or 6,000-12,000 kilopond-meters/20 min) was well-tolerated by all patients. Some enzyme activities showed significant changes 45 min after loading. In group 1, ALD-M was 64% of the pretest level; ALD-L 142%, SGOT-T 111%, and SGOT-M 123%; in group 2, SGOT-T was 118%, SGOT-M 122%; in group 3, SGOT-M was 140%. By 22 hr, though, all enzyme activities had returned to normal, and they were not significantly different from pretest values. The short-term increase of ALD-L, SGOT-M, and SGOT-T indicates the involvement of liver cells in the loading test. However, these enzyme assays are insufficient for determining the rehabilitation date of an individual patient in terms of ability to work.

LIVER AND BILIARY TRACT

Chronic Hepatitis

7798 ANTIMITOCHONDRIAL ANTIBODIES IN CHRONIC PERSISTANT HEPATITIS. (Ita.) Di Marco, G.; Vandelli, C. (Istituto di Clinica Medica Generale e Terapia Medica dell'Universita di Modena, Modena, Italy). *Minerva Gastroenterol.* 22(3):199-206; 1976.

Circulating antinuclear (ANA), antimitochondrial (AMA), and anti-smooth muscle (SMA) antibodies were determined by immunofluorescence in 114 patients with chronic active hepatitis (CAH), 13 patients with primary biliary cirrhosis (PBC), and twenty-five normal subjects. The serum levels of SGOT, SGPT, bilirubin, cholesterol, IgA, IgG, and IgM, and the presence or absence of hepatitis B surface antigen (HBsAg) were determined. Based upon the presence of AMA, CAH patients were divided into two groups: group A was AMA-negative but ANA-, SMA-, and HBsAg-positive; group B, which consisted almost entirely of HBsAg-negative women, was AMA-positive with evidence of cholestasis. Group B was also hypercholesterolemic and had high IgM levels and high levels of biliary secretion. Differences in SGPT and SGOT levels between CAH group A patients and PBC patients were statistically significant; this difference was not so apparent between CAH group B patients and PBC patients. These patients had been classified histologically as CAH rather than PBC patients. PBC patients were also AMA-negative. AMA is useful in distinguishing between cases of CAH and PBC, especially when the CAH patients have characteristics in common with PBC.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7802 CHANGING PATTERN OF ALCOHOLIC LIVER DISEASE IN GREAT BRITAIN: RELATION TO SEX AND SIGNS OF AUTOIMMUNITY. (Eng.) Krasner, N.; Davis, M.; Portmann, B.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5, England). *Br. Med. J.* 1(6075):1497-1500; 1977.

The frequency and prognosis of alcoholic liver disease and the presence or absence of autoantibodies in patients with this disease were compared in 78 women and 215 men. The male:female ratio decreased over the period of the survey due to a significant increase in the proportion of women referred (4.88:1 in 1967-71, compared with 2.11:1 in 1972-75; $p< 0.01$). The incidence of fatty infiltration was significantly higher in men than in women (46/54, $p<0.05$), whereas the incidence of central sclerosing hyaline necrosis was greater in women than in men (9/16, $p<0.025$). When the pattern of liver damage was analyzed according to age, the preponderance of central sclerosing hyaline necrosis was confined to women under 55 yr (30.8%), particularly those aged under 45. There was also a significantly higher incidence among women of both alcoholic hepatitis, with or without cirrhosis ($p< 0.001$), and alcoholic hyaline (60.2% of women versus 34.8% of men, $p< 0.0005$). However, 13 of the 14 patients with hepatoma were men; if patients with cirrhosis only were considered, hepatoma occurred nearly five times more often in men than in women (9.63% and 2.04%, resp.). There was a significant increase in the incidence of smooth muscle antibodies in women with cirrhosis and alcoholic hepatitis (45.4%) compared with the incidence in men (23.4%, $p<0.05$), and this difference was also the case for antinuclear antibodies (31.8% and 8.5%, resp., $p<0.05$). Among patients with histological abnormalities, the mean serum IgG and IgM levels were higher in women than in men (2.076 ± 0.227 versus 1.523 ± 0.192 g/l, $p< 0.05$, and 5.087 ± 1.077 versus 2.616 ± 0.338 g/l, $p< 0.02$, resp. Only 41% of patients who continued to drink were alive at the 5-yr follow-up in contrast to 60% of those who abstained ($p< 0.05$). Overall, men derived significantly greater benefit from abstaining than women; all but one of the 16 men who died had continued to drink, while 9 of the 20 women who died claimed to have stopped drinking ($p<0.05$). These studies suggest that immune mechanisms may play a part in the pathogenesis and progression of alcoholic liver disease in women.

7803 HISTOLOGICAL CHANGES IN THE LIVER AND INDICES OF DRUG METABOLISM IN ALCOHOLICS. (Eng.) Sotaniemi, E. A.; Ahlqvist, J.; Pelkonen, R. O.; Pirttiaho, H.; Luoma, P. V. (Dept. Internal Medicine, Univ. Oulu, SF-90220 Oulu 22, Finland). *Eur. J. Clin. Pharmacol.* 11(4):295-303; 1977.

To test the hypothesis that the ability of alcoholics to metabolize drugs might be related to parenchymal alterations in the liver, 27 chronic alcoholics underwent liver biopsy and, 1 day later, received antipyrine (20 mg/kg, p.o.). Venous blood samples were taken at zero time and 1, 3, 6, 9, 12, 24, 48, and 72 hr later, and the plasma antipyrine level was assessed by gas-liquid chromatography. Histologically, the patients could be divided into four groups: patients with a normal or fatty liver and patients with alcoholic hepatitis or cirrhosis. Patients with a normal liver had a significantly higher amount of hepatic cytochrome P-450 than those with a fatty liver, hepatitis, or cirrhosis. Alcoholics with a normal or fatty liver metabolized antipyrine significantly faster than alcoholics with hepatitis or cirrhosis.

7804 SERUM IMMUNOGLOBULIN A CHANGES IN ALCOHOLIC PATIENTS. (Eng.) Iturriaga, H.; Pereda, T.; Estevez, A.; Ugarte, G. (Instituto de Nutricion y Tecnologia de los Alimentos, Casilla 15138, Santiago 11, Chile). *Ann. Clin. Res.* 9(1):39-43; 1977.

To assess the diagnostic value of determining the serum IgA concentration in alcoholics, IgA and IgG concentrations were determined in 8 alcoholics with normal liver, 7 alcoholics with fatty liver, 8 alcoholics with acute alcoholic hepatitis, 8 alcoholics with fibrosis or cirrhosis, 36 alcoholics with liver failure, 22 nonalcoholic patients with varying degrees of liver failure, and 100 controls. Serum IgA concentrations in the alcoholics with normal liver histology (377.2 ± 37.5 mg%), alcoholics with fatty liver (396.6 ± 54.6 mg%), alcoholics with alcoholic hepatitis (524.4 ± 42.0 mg%), alcoholics with cirrhosis (525.4 ± 98.7 mg%), alcoholics with liver failure (926.6 ± 77.4 mg%), and nonalcoholics with liver damage (357.6 ± 24.0 mg%) were significantly increased in comparison with the controls (248.8 ± 9.3 mg%; $p<0.05$, $p<0.01$, $p<0.001$, $p<0.01$, $p<0.001$, and $p<0.001$ for each group, resp.). IgG concentrations were also raised, but a significantly increased level was only observed in groups with liver damage. There was a clear correlation between IgA concentration and the degree of liver abnormality ($r=1$, $p<0.01$). Using the ratio of IgA/IgG, alcoholics with liver damage could be differentiated from nonalcoholic patients with liver damage. In the alcoholics with liver failure, the IgA and IgG values were similar for patients with short or long abstinence periods. Alcoholic patients with severe liver failure (i.e., two or more of the following: encephalopathy, prothrombin time <30%, total bilirubin >5.0 mg%, serum albumin <1.5 g%) had significantly higher IgA levels than did those with moderate liver failure. The results confirm a remarkable increase in serum IgA concentration in alcoholic patients. The increase in alcoholics without liver damage has not been reported previously.

7805 ALTERATIONS OF LIPID METABOLISM IN HEALTHY VOLUNTEERS DURING LONG-TERM ETHANOL INTAKE.

(Eng.) Belfrage, P.; Berg, B.; Hagerstrand, I.; Nilsson-Ehle, P.; Tornqvist, H.; Wiebe, T. (Dept. Physiol. Chem. 4, Box 750, S-220 07 Lund 7, Sweden). *Eur. J. Clin. Invest.* 7(2):127-131; 1977.

Lipid metabolism was studied in nine healthy men during long-term ethanol intake. The men received ethanol (75 g/day) for 5 weeks. The ethanol was divided into five daily doses and taken so that blood ethanol levels never exceeded 0.04% (weight/volume). During the latter part of the ethanol intake period, there was a significant, transient increase of plasma triglyceride (TG) concentrations followed by reduction to normal levels. A threefold increase in lipoprotein lipase activity (LLA) occurred in biopsy specimens of adipose tissue. An increase of α-lipoprotein concentrations, which correlated significantly with the decrease in plasma TG levels and the increase in adipose LLA, was also observed during the ethanol intake period. No changes were observed in plasma cholesterol and β-lipoprotein levels. A transient, threefold increase of TG concentrations occurred in liver biopsy specimens. Ultrastructural and cytochemical examinations of the biopsy specimens showed hyperplasia of the smooth endoplasmic reticulum, and increased canalicular activity of γ-glutamyl transferase (γ-GT) activity in most subjects towards the end of and after the ethanol intake period. Serum γ-GT levels also increased significantly.

7806 PROTEIN SYNTHESIS AND RELEASE BY LIVER BIOPSY SPECIMENS FROM PATIENTS WITH CHRONIC ALCOHOLIC LIVER DISEASE.

(Eng.) Agostini, C.; Mortara, G.; Curti, M. T.; Pace, G.; Saraceno, G. (Istituto di Patologia Generale, Universita di Milano, Via Mangiagalli, 31, 20133 Milan, Italy). *Rend. Gastroenterol.* 9(1):18-23; 1977.

The effect of alcohol on the synthesis and release of liver proteins was studied in 48 chronic alcoholic patients. The patients underwent liver biopsy, and the specimens were incubated with Ringer's solution containing 2 µCi of ^{14}C-leucine for 4 hr and then homogenized for conventional protein assay. Histomorphologically, 5 liver specimens were found to be normal, 14 showed symptoms of steatosis, 14 of chronic hepatitis, and 15 of cirrhosis. Incorporation of leucine into the hepatic proteins was increased significantly ($0.06>p>0.05$) only in the cirrhosis patients (30,757 counts/min/mg protein, compared to 26,036 in the chronic hepatitis patients, 21,515 in the steatosis patients, and 19,760 in the patients with a morphologically normal liver). Although the amount of released protein was somewhat greater in the patients with steatosis, chronic hepatitis, or cirrhosis, the difference was not statistically significant.

7807 ALCOHOLIC LIVER INJURY.

(Eng.) Williams, R.; Davis, M. (King's Coll. Hosp. and Medical Sch., London SE5, England). *Proc. R. Soc. Med.* 70(5):333-337; 1977.

Patterns of alcoholic liver injury, factors determining the development of alcoholic liver disease, and the role of sex in determining susceptibility to alcoholic liver injury are reviewed. Fatty infiltration of the liver is the earliest lesion detected, and uncomplicated infiltration is generally considered to be benign and readily reversible when alcohol is withdrawn. Alcoholic hepatitis is characterized by necrosis with inflammatory cell infiltration, and the mortality from this condition is 10-30%. Alcoholic cirrhosis is classically micronodular with bands of fibrosis linking adjacent portal tracts and centrilobular areas to produce nodules of lobular size or smaller. It has been estimated that only 30% of heavy drinkers will develop alcoholic hepatitis, and 10% cirrhosis. Although the majority of alcoholics have fatty changes on liver biopsy, up to one-third have no demonstrable abnormality. The mechanism of liver cell necrosis in acute alcoholic hepatitis is not well understood, but possibilities include direct toxicity of alcohol or one of its metabolites, and immune factors. Some studies have suggested that women, particularly those under 45 yr, are more susceptible to cirrhosis and superimposed alcoholic hepatitis. The average age of death for women with cirrhosis was found to be almost 11 yr less than that for men, and women had a higher mortality when they continued to drink.

7808 ADRENOCORTICOSTEROID THERAPY IN ALCOHOLIC HEPATITIS. A PROSPECTIVE, DOUBLE-BLIND

RANDOMIZED STUDY. (Eng.) Blitzer, B. L.; Mutchnick, M. G.; Joshi, P. H.; Phillips, M. M.; Fessel, J. M.; Conn, H. O. (Section Diseases Liver, NIAMDD, NIH, Bethesda, MD 20014). *Am. J. Dig. Dis.* 22(6):477-485; 1977.

The efficacy of adrenocorticosteroid therapy for acute alcoholic hepatitis was evaluated in 33 patients with acute active alcoholic liver disease. These patients were culled from a group of 80 patients who did not meet the admission criteria of a recent history of heavy alcohol consumption, hepatomegaly, total serum bilirubin >5 mg/100 ml, and at least two of the following: SGOT >100 Reitman-Frankel U/ml, serum albumin concentration <3 g/100 ml, or prothrombin time >2 sec over control value. The patients were randomized into two groups: 17 patients were assigned to receive prednisolone, p.o. (10 mg q.i.d. for 14 days, 5 mg q.i.d. for 4 days, 2.5 mg q.i.d. for 4 days, and 2.5 mg b.i.d. for 4 days), and 17 patients were assigned to receive a placebo according to the same schedule. Subsequently, five steroid group patients left the study and were excluded from the analysis. Of the 28 remaining patients, 11 died during hospitalization (6/12 in the steroid group, 5/16 in the placebo group). Gastrointestinal hemorrhage, the hepatorenal syndrome, spontaneous peritonitis, and fungal infections accounted for most of the deaths. There was no significant difference between the two groups in the percentage decrease of serum bilirubin levels during therapy; SGOT and prothrombin time were also similar in the two groups. After 14 days of treatment, mean WBC count and serum albumin concentration were significantly higher in the steroid group. Since the overall mortality and cumulative survival of the patients were not significantly different in the placebo- and prednisolone-treated groups, it was concluded that continuation of treatment would be fruitless.

LIVER AND BILIARY TRACT

Cirrhosis

7811 HUMAN HEPATIC δ-AMINOLAEVULINATE SYNTHASE: REQUIREMENT OF AN EXOGENOUS SYSTEM FOR SUCCINYL-COENZYME A GENERATION TO DEMONSTRATE INCREASED ACTIVITY IN CIRRHOTIC AND ANTICONVULSANT-TREATED SUBJECTS. (Eng.) Bonkowsky, H. L.; Pomeroy, J. S. (Hepatology Res. Lab., Veterans Admin. Center, White River Junction, VT 05001). *Clin. Sci. Mol. Med.* 52(5):509-521; 1977.

δ-Aminolevulinate (ALA) synthase activity was assessed in liver biopsy specimens from 12 patients with cirrhosis, 5 noncirrhotic patients with seizure disorders treated with anticonvulsants, and 16 healthy controls. Within 1 or 2 days of the biopsy, the patients underwent 24-hr urine collection, and the excretion of porphyrins and their precursors was determined. In the liver homogenates, ALA synthase activity was measured in the presence and absence of an exogenous system for the generation of succinyl-coenzyme A (CoA) that included succinic thiokinase (STK). In the absence of exogenously added STK plus other reagents for the optimum generation of succinyl-CoA, the mean rate of ALA formation was practically identical in homogenates of control subjects (217 U) and both the cirrhotic (193 U) and anticonvulsant-treated (220 U) patients. However, when STK was added, the mean rate of ALA formation in the cirrhotic (1,297 U) and anticonvulsant-treated (1,128 U) patients was significantly greater than that in controls (548 U). Cirrhotic patients excreted more uroporphyrin, but the anticonvulsant-treated patients showed a slightly elevated excretion of porphobilinogen.

7812 CARBOHYDRATE CONTENT OF HUMAN RED CELL MEMBRANE IN PATIENTS WITH CIRRHOSIS OF THE LIVER. (Eng.) Gattegno, L.; Fabia, F.; Cornillot, P. (Laboratoire de Biochime, U.E.R. Experimentale de Medecine et de Biologie Humaine, 74, rue Marcel Cachin, 93000 Bobigny, France). *Clin. Chim. Acta* 77(3):317-321; 1977.

The protein and carbohydrate contents of RBC membranes from 12 patients with liver cirrhosis were compared with those from 12 normal donors, and the effects of RBC aging on these factors were investigated in both groups. The neutral hexoses, sialic acid, fucose, and hexosamine levels were significantly lower in RBC ghosts from cirrhotic patients (40 ± 4, 12.5 ± 1.0, 12.0 ± 1.5, and 12.2 ± 1.2 μg/mg membrane protein, resp.) than those in the healthy subjects (55 ± 5, 17.5 ± 1.0, 21.0 ± 1.8, and 25.0 ± 5.0 μg/mg, resp.; $p<0.001$), and the protein level in the cirrhotic patients (5.51 ± 0.34 mg/ml membrane protein) was significantly higher than that in the normal subjects (4.08 ± 0.60 mg/ml, $p<0.001$). The carbohydrate and protein levels were lower in old RBC membranes than in young membranes of the normal subjects. The carbohydrate levels in membranes from the cirrhotic patients were even lower than the levels in old membranes from the normal subjects. These data suggest that the molecular arrangement of the cirrhotic patients' RBC membrane carbohydrates may differ from that observed in normal subjects. The fact that surface membrane carbohydrates of normal human RBC are significantly decreased with *in vivo* aging suggests the possibility that surface membrane carbohydrates of human RBC might be implicated in the clearance of these RBC.

7813 ABNORMAL FIBRINOGEN HETEROGENEITY AND FIBRINOLYTIC ACTIVITY IN ADVANCED LIVER DISEASE. (Eng.) Lipinski, B.; Lipinska, I.; Nowak, A.; Gurewich, V. (St. Elizabeth's Hosp., 736 Cambridge St., Boston MA 02135). *J. Lab. Clin. Med.* 90(1):187-194; 1977.

Fibrinogen heterogeneity and fibrinolytic activity were studied in the blood of 11 patients with Laennec's cirrhosis, 11 patients with chronic aggressive hepatitis, and 25 healthy controls. The findings in the cirrhotic and active hepatitis patients were similar and are thus presented together. The fibrinolytic activity of the euglobulin fractions was significantly greater ($p<0.01$) in the 22 patients (105 mm^2; range, 80-221 mm^2) than in the controls (72 mm^2; range, 38-175 mm^2). The plasminogen antiactivator content of the patients was only 40% ± 30% of the control level ($p<0.001$), but their total fibrinogen concentration (336 ± 125 mg/100 ml) was not significantly different from that of controls (305 ± 91 mg/100 ml). Plasma electrophoresis studies showed that the concentration of high molecular weight (HMW) fibrinogen was significantly lower ($p<0.001$) in patients (130 ± 82 mg/100 ml) than in controls (203 ± 71 mg/100 ml) and that concentrations of two low molecular weight fractions (LMW and LMW^1) were significantly higher ($p<0.001$) in patients (162 ± 75 and 45 ± 44 mg/100 ml, resp.) than in controls (96 ± 34 and 6 ± 12 mg/100 ml, resp.). In 2/22 patients, the HMW fraction was virtually absent. *In vitro* incubation (37 C for 48 hr) of diluted (1:10) plasma from a patient resulted in almost 50% degradation of a low solubility fibrinogen fraction (HMW) previously added to the sample as well as the appearance of the LMW and LMW^1 fractions. No HMW degradation was observed in an undiluted plasma sample from the same patient. Also, none of the plasma samples from normal subjects after venous occlusion (diluted or undiluted) showed any fibrinogen degradation after 48 hr of incubation. It is concluded that the increased concentration of LMW forms of fibrinogen in the blood of patients with liver disease is probably related to increased *in vitro* degradation rather than to abnormal synthesis.

7814 PLATELET MONOAMINE OXIDASE, PLASMA BENZYLAMINE OXIDASE AND LIVER MIXED FUNCTION OXIDASE IN CIRRHOTIC PATIENTS. (Eng.) Buffoni, F.; Ignesti, G.; Pirisino, R.; Cortesini, C. (Dept. Pharmacology, Univ. Florence, Viale G.B. Morgagni 65, 50134 Florence, Italy). *Med. Biol.* 55(2):109-111; 1977.

The level of monoamine oxidase (MAO) was studied in the liver and platelets of 23 cirrhotic patients, because a decrease in MAO might explain the increase in false neurotransmitters observed in cirrhotic patients. Plasma benzylamine oxidase (BAO) activity and liver mixed function oxidases (MFO) were also investigated. The plasma BAO activity was higher in the cirrhotic patients, but the difference in comparison with 17 controls with cholelithiasis was not statistically significant. The platelet and liver MAO activities in the 13 patients with severe liver cirrhosis (3.54 ± 1.10 and 134 ± 28 nmol substrate oxidized/mg protein/30 min, resp.) were significantly lower than those in controls (8.86 ± 1.45 and 225 ± 29 nmol of substrate oxidized/mg protein/30 min, resp.). Both plasma and platelet oxidases significantly increased in the cirrhotic patients after portacaval shunt. The decrease in MAO activity in both liver and platelets in the cirrhotic patients may support the suggestion that an accumulation of false neurotransmitters occurs, since their precursors are normally degraded by these enzymes.

7815 FAMILIAL HEMOCHROMATOSIS: CHARACTERISTICS OF THE PRECIRRHOTIC STAGE IN A LARGE KINDRED. (Eng.) Rowe, J. W.; Wands, J. R.; Mezey, E.; Waterbury, L. A.; Wright, J. R.; Tobin, J.; Andres, R. (Beth Israel Hosp., Boston, MA 02215). *Medicine (Baltimore)* 56(3):197-211; 1977.

A large family with idiopathic hemochromatosis, in which most of the affected members were in the precirrhotic stage, was studied. The proband, a 54-yr-old man, had clinical manifestations of hemochromatosis. Diagnosis was confirmed upon liver biopsy, which showed macronodular cirrhosis with marked iron deposition in the hepatocytes and Kupffer cells. His family was studied systematically in an attempt to identify members with iron overload; 50 asymptomatic members over the age of 13 yr, spanning three generations, were examined. Liver biopsy specimens were obtained from 31 of these subjects. Increased hepatic parenchymal iron deposition, selected as a marker for the hemochromatosis gene, was present in all 3 generations and in 20/31 specimens. These findings are consistent with an autosomal dominant mode of inheritance with incomplete expressivity. Hepatic fibrosis was seen in six biopsies, but the presence and extent of fibrosis did not correlate with the severity of iron deposition but rather with a history of significant alcohol intake. Serum iron was significantly higher in family members with iron overload (135 ± 11.27 mg/100 ml, compared to 103.2 ± 7.03 mg/100 ml in unaffected members). Transferrin saturation was also greater in the affected members (43.4 ± 3.99% versus 29.9 ± 3.26%). The results of a p.o. glucose tolerance test and an i.v. insulin tolerance test showed that carbohydrate tolerance was impaired in the precirrhotic stage of hemochromatosis, the degree of impairment being related to the severity of iron deposition.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

7823 ULTRASOUND: A NEW DIAGNOSTIC APPROACH TO THE JAUNDICED PATIENT. (Eng.) Tsikoff, M. B.; Diaconis, J. N. (Jackson Memorial Hosp., Miami, FL 33141). *JAMA* 238(3):221-223; 1977.

The accuracy of ultrasound in differentiating between intra- and extrahepatic biliary obstruction was studied in 40 patients. Of the 24 patients in whom ultrasound suggested that jaundice was caused by extrahepatic obstruction, this was subsequently verified by surgery or liver biopsy in 23. Of the 16 cases showing no evidence of obstruction, six were confirmed as hepatocellular disease by liver biopsy specimens, and an additional nine were followed medically for periods of 3-9 months, their clinical course being consistent with a diagnosis of intrahepatic cholestasis. Thus, there was one false-positive and one false-negative in this series. Ultrasound can be used routinely to differentiate extrahepatic biliary obstruction from intrahepatic cholestasis. It is noninvasive, has no associated morbidity or mortality, and is considerably less expensive than endoscopic retrograde cholangiopancreatography or transhepatic cholangiography.

7824 CHENODEOXYCHOLIC ACID IN THE MANAGEMENT OF GALL STONES. (Eng.) Batey, R. G. (Royal Free Hosp., Pond St., Hampstead, London NW3 2QG, England). *Drugs* 14(2):116-119; 1977.

The efficacy, toxicity, and mechanisms of action of chenodeoxycholic acid (CDCA) in the treatment of gallstones are reviewed. Possible mechanisms in the production of lithogenic bile and the indications for the use of CDCA in the treatment of cholelithiasis are also discussed. Excessive bile salt loss, oversensitive bile acid feedback, excessive cholesterol secretion, and primary disorders of the gallbladder, bile ducts, or sphincter mechanisms are among the possible mechanisms in the production of lithogenic bile. The ways in which CDCA decreases biliary cholesterol secretion include a drug-induced increase in the bile acid pool, an impairment of enzymes within the cholesterol/bile acid pathway, and a reduction in intestinal cholesterol absorption. Several trials have confirmed the original finding that CDCA, administered in sufficient dosage, leads to the dissolution of cholesterol gallstones in more than 50% of patients. The effectiveness of CDCA therapy depends on the dose used (usually 13-15 mg/kg, but sometimes 18-20 mg/kg), the duration of therapy (usually 6-24 months), and the timing of administration (in the evening as opposed to the morning). The only significant side-effect of CDCA therapy to date has been mild diarrhea, which usually responds to the administration of small doses of cholestyramine. CDCA therapy is usually instituted in poor surgical risks (old or sick patients), patients with anatomical abnormalities of the biliary tree associated with cholelithiasis, and other patients refusing surgery on medical or personal grounds; however, recent work suggests that such therapy may be of value in a wider group of patients. Apparent drug failure should lead to the following steps before the drug is abandoned: an increase in the dosage and a change from morning to nocturnal dosage schedule.

7825 HILAR HEPATOJEJUNOSTOMY IN RESECTION OF CARCINOMA OF THE MAIN HEPATIC DUCT JUNCTION.

(Eng.) Karakousis, C. P.; Douglass, H. O., Jr. (General Surgery Dept. Roswell Park Memorial Inst., Buffalo, NY). *Surg. Gynecol. Obstet.* 145(2):245-248; 1977.

The cases of two male patients, 65 and 52 yr old, with carcinoma of the main hepatic junction in whom reconstruction of the biliary outflow was carried out by hepatojejunostomy are described. Resection followed by reconstruction between a Roux-en-Y loop of jejunum and the hepatic tissue surrounding the bile ducts at the hilum of the liver was carried out in both cases. At 18 and 11 months after surgery, resp., both patients are free from known tumor recurrence and both have normal serum bilirubin levels. Hepatojejunostomy appears to be a safe alternative reconstruction following resection of carcinomas of the proximal hepatic duct.

7826 ON THE CHEMISTRY OF HUMAN PIGMENT GALLSTONES.

(Eng.) Wosiewitz, U.; Schroebler, S. (Institut fur Medizinische Physik der Universitat, D-4400 Munster, W. Germany). *Naturwissenschaften* 64(6):340; 1977.

The chemistry of human pigment gallstones was studied by thin-layer chromatography. Samples submitted to chromic acid degradation for 1 hr (25 C) gave a positive reaction with benzidine when treated beforehand with chlorine. The degradation products of bilirubin, biliverdin, and urobilin reacted in the same way, but not those of melanin. The same material submitted to chromate degradation gave a characteristic reaction with 2,4-dinitrophenylhydrazine. Degradation products of natural melanin did not react spontaneously but gave uncharacteristic colored spots when heated (110 C) for about 30 min. Undefined, barely soluble material from extracted pigment stones and natural melanin, both submitted to the same oxidative degradation conditions, yielded very different degradation products. Thus, pigment stone material and melanin are not identical. The thin-layer chromatograms suggested that pigment stone material turns into maleimides and pyrroledialdehydes during the chromic acid and chromate oxidation; this is also known to be the case for bile pigments. It is thus postulated that residues of pigment stone extractions are derived from bile pigments.

7827 SIGNIFICANCE OF LOW-DENSITY LIPOPROTEIN (LP-X) TEST IN THE DIAGNOSIS OF CHOLESTASIS.

(Ger.) Michel, B.; Ritter, U. (I. Medizinische Klinik, Med. Hochschule Lubeck, Kronsforder Allee 71/73, D-2400 Lubeck, W. Germany). *Z. Gastroenterol.* 14(5):556-569; 1976.

The value of the low-density lipoprotein test (LP-X test) in the diagnosis of cholestasis was determined in 73 patients with hepatobiliary diseases. These diseases were diagnosed morphologically in 53 patients, 27 of whom had cholestasis (6 with obstructive jaundice due to tumor, 7 with cholelithiasis, 4 with hepatitis, 7 with cirrhosis, and 3 with nutritive and toxic liver damage). The LP-X test was positive in 25/27 patients and falsely negative in 2 (1 with cholelithiasis and 1 with diabetes plus advanced cirrhosis). Twenty-six patients did not have cholestasis; the LP-X test was negative in 23/26 patients, falsely positive in 3 (1 with suppurative cholangitis against a background of liver cirrhosis and fatty degeneration, 1 with hepatitis and fatty degeneration following alcohol abuse, and 1 with chronic esophagitis and fibrosing fatty degeneration). Hepatobiliary diseases were diagnosed clinically in 20 patients, 12 of whom had cholestasis (7 with cholelithiasis, 4 with hepatitis, and 1 with nutritive and toxic liver damage). The LP-X test was positive in all cases. The eight patients without cholestasis had negative LP-X tests. The findings indicate that the LP-X test is a reliable and simple tool for the diagnosis of cholestasis, but that it is unsuitable for differentiating between intrahepatic and extrahepatic cholestasis. The etiology of jaundice cannot be established from a positive test. However, it permits the diagnosis of cholestasis with clinically normal alkaline phosphatase activity. The LP-X test is highly sensitive and specific for diagnosing borderline cases of cholestasis when it is combined with the γ-glutamyltranspeptidase alkaline phosphatase test.

GENERAL

7853 TOTAL PARENTERAL NUTRITION IN MALNOURISHED INFANTS WITH INTRACTABLE DIARRHEA. (Eng.) Gunn, T.; Brown, R. S.; Pencharz, P.; Colle, E. (Montreal Children's Hosp., 2300 Tupper St., Montreal, Quebec H3H 1P3, Canada). *Can. Med. Assoc. J.* 117(4): 357-360; 1977.

Experience with total parenteral nutrition (TPN) in the treatment of 34 infants with protein-energy malnutrition and intractable diarrhea is presented. TPN consisted of casein hydrolysate, a soybean emulsion, and dextrose. Initially, peripheral veins were used in all infants, and 22 were treated successfully without the necessity of resorting to a central venous catheter. The mean duration of treatment by the peripheral route was 29 days. Although the mean energy intake and protein intake were high, weight gain was poor, and growth continued at the prehospitalization percentiles. There were two deaths, due to complications resulting from the use of the central venous catheter. Specific diagnoses were established for 7 of the 9 Caucasian infants but only 2 of the 25 Inuit infants. SGOT concentrations were elevated in 80% of the patients at the time of admission, increased further in 82% when TPN was begun, but decreased towards normal before discharge in all patients. Eosinophilia was common during TPN. Liver biopsy in seven patients with elevated SGOT values showed eosinophilia, increased pigment in the Kupffer cells, and slight lymphocytosis in the portal tract. Intercurrent infections occurred frequently and were often preceded by a short period of lipid intolerance or neutropenia, or both. Tolerance to lipids returned after the infections resolved. Peripheral TPN is a safe and relatively simple method of providing adequate nutrition during episodes of diarrhea in malnourished infants.

7854 DOUBLE-BLIND TRIAL OF CHOLESTYRAMINE IN POSTVAGOTOMY DIARRHOEA. (Eng.) Duncombe, V. M.; Bolin, T. D.; Davis, A. E. (Prince of Wales Hosp., Randwick, Sydney, New South Wales, Australia). *Gut* 18(7):531-535; 1977.

The effect of cholestyramine in postvagotomy diarrhea was assessed in a double-blind study of 20 patients who had undergone truncal vagotomy 1-15 yr earlier. Cholestyramine (4 g x 4/day, p.o.) produced a significant improvement in frequency, urgency, and consistency of stool as well as episodic diarrhea. Fecal bile acid excretion was significantly higher in the postvagotomy group (1,024 mg/day) when compared with normal controls (473 mg/day, $p<0.0025$). These findings confirm the effectiveness of cholestyramine and support the concept of a bile acid-mediated etiology in postvagotomy diarrhea.

7855 THE CHICAGO VARIANT OF CLINICAL GALACTOSEMIA. (Eng.) Chacko, C. M.; Wappner, R. S.; Brandt, I. K.; Nadler, H. L. (Northwestern Univ. Medical Sch., 2300 Children's Plaza, Chicago, IL 60614). *Hum. Genet.* 37(3):261-270; 1977.

A new variant of clinical galactosemia with two hitherto unidentified alleles at the transferase locus in one family is described. The patient developed symptoms (anorexia, light-colored stools, mild jaundice, and a slightly enlarged liver) by 8 weeks of age. The patient became asymptomatic on a galactose-free diet. At 2 yr of age, he was challenged with galactose. After 1 week of normal galactose intake, the galactose-1-phosphate level in the RBC had risen to 7.9 mg/100 ml. The patient was thus restarted on a galactose-restricted diet. The new clinical variant of transferase was found to have 25% of normal control activity in blood and in skin fibroblasts. Using starch gel electrophoresis on hemolysates of the patient's family members, a fast-moving transferase with mobility in between those of the normal control and of the Duarte variant was identified. This new allele was designated GALT^{C1} (fast-moving Chicago variant). In addition, a second new allele was documented in this family by studying the instability of the transferase enzyme in hemolysates of family members at 50 C for various time intervals. This new allele was designated GALT^{C2} (heat-labile Chicago variant). The transferase genotype of this patient is thought to be a double heterozygote compound, GALT^{C1}/GALT^{G}.

7856 SERUM PROTEINASE INHIBITORS AND OTHER SERUM PROTEINS IN PROTEIN-ENERGY MALNUTRITION. (Eng.) Schelp, F. P.; Migasena, P.; Pongpaew, P.; Schreurs, W. H. P.; Supawan, V. (Dept. Tropical Nutrition, Mahidol Univ., Bankok 4, Thailand). *Br. J. Nutr.* 38(1):31-38; 1977.

The concentrations of serum protein albumin, prealbumin, and transferrin were determined in 28 patients with protein-energy malnutrition (PEM) with infection, together with the levels of serum proteinase inhibitors (PI), α_1-antitrypsin (AT), α_1-antichymotrypsin (Ach), α_2-macroglobulin (α_2M), and inter-α-trypsin inhibitor (IαI). Albumin, prealbumin, transferrin, IαI, and α_2M concentrations in Thai and Indonesian children (21 ± 1.8 and 29 ± 2.0 g/l, 40 ± 10.8 and 53 ± 11.5 mg/l, 1,005 ± 189 and 1,196 ± 241 mg/l, 795 ± 86 and 1,092 ± 90 U/l, and 3,192 ± 370 and 3,336 ± 299 mg/l, resp.) were lower in cases of PEM associated with infection than the corresponding values for 28 healthy Thai preschool children (48 ± 2.0 g/l, 160 ± 11.1 mg/l, 3,034 ± 121 mg/l, 1,106 ± 31 U/l, and 4,588 ± 184 mg/l, resp.) and a group of newborn Thai children. Despite starvation, AT and Ach values were generally increased. The results support the hypothesis that PI, especially AT and Ach might limit the synthesis of albumin, prealbumin, and transferrin in PEM associated with infection, via the inhibition of the mobilization of the body's own protein.

GENERAL

Parasitology

7892 GIARDIASIS: CLINICAL AND THERAPEUTIC ASPECTS. (Eng.) Wright, S. G.; Tomkins, A. M.; Ridley, D. S. (Hosp. Tropical Diseases, London, England). *Gut* 18(5):343-350; 1977.

The clinical and therapeutic aspects of 40 cases of symptomatic giardiasis in which malabsorption was common and vitamin B_{12} malabsorption was particularly frequent are reported. Malabsorption was present in 29 of the 40 patients. Twenty-three had impaired D-xylose absorption; in 20, vitamin B_{12} absorption was low, and 15 patients had steatorrhea. More severe malabsorption was associated with more marked histological abnormalities. Metronidazole (2.0 g/day) on 3 successive days, produced a parasitological cure rate of 91%. In contrast, the standard course of mepacrine (100 mg t.i.d.) for 10 days eradicated the parasite in only 63% of patients. Improvements in absorption and jejunal morphology followed anti-giardial treatment. Tetracycline (250 mg q.i.d.) for 4 weeks failed to eradicate the parasite in seven of eight patients; intestinal absorption was unaltered, and histological appearances of the jejunal mucosa often deteriorated. The satisfactory therapeutic response to the eradication of *G. lamblia* with improvement of mucosal function and morphology suggests a pathogenic role for the parasite.

7893 CYTOCHEMICAL LABELING OF PROTEOLYTIC ENZYMES IN E. histolytica. (Spa.) Gonzalez-Garza, M. T.; Arellano-Blanco, J.; Gomez-Estrada, H. (Instituto Mexicano del Seguro Social. Apdo. Postal 73-032, Mexico 12, D. F.). *Arch. Invest. Med. (Mex.)* 8(2):139-144; 1977.

GENERAL

Regional Enteritis

7896 HL-A B27 ANTIGEN IN CROHN'S DISEASE ASSOCIATED WITH RHEUMATOID SPONDYLARTHRITIS AND IN A NORMAL POPULATION. (Fre.) de Bruyere, M.; Nagant De Deuxchaisnes, Ch.; Fiasse, R.; Huaux, J. P.; De Vogelaer, J. P. (Services d'Hematologie, Cliniques Universitaires Saint-Pierre, Louvain, Belgium). *Rev. Fr. Transfus. Immunohematol.* 20(1):31-34; 1977.

The incidence of the histocompatibility antigen (HL-A) B27, previously found to be associated with ankylosing spondylarthritis (AK), was compared in blood samples from 26 patients with AK + Crohn's disease (CD), 47 with Crohn's disease, 108 with AK, and 250 normal blood donors. The 26 AK+CD patients were screened from a group of 122 CD patients; 15/26 had symptoms of chronic low back pain and x-ray evidence of changes in the sacroiliac vertebrate, 7 had asymptomatic radiological changes in the spine, and 4 were diagnosed as probable AK. HL-A B27 was found in 8.4% of the normal subjects, 81% of the AK patients, none of the CD patients, 5/15 patients with classic AK + CD, and 0/11 patients with asymptomatic AK + CD.

7897 DOUBLE-BLIND PLACEBO-CONTROLLED STUDY OF LOPERAMIDE (IMODIUM) IN CHRONIC DIARRHOEA CAUSED BY ILEOCOLIC DISEASE OR RESECTION. (Eng.) Mainguet, P.; Fiasse, R. (Cliniques Universitaires St. Pierre, B-3000 Louvain, Belgium). *Gut* 18(7): 575-579; 1977.

Loperamide (R 18 553) was compared with a placebo in a double-blind crossover study of 18 patients with chronic diarrhea caused by ileocolic disease or resection. At a median daily dose of 6 mg, the new antidiarrheal preparation was superior to the placebo in controlling chronic diarrhea. The frequency and weight of stools significantly decreased ($p<0.001$ in both cases), the stools became more solid ($p<0.001$), and carmine transit time was prolonged (2.25 versus 4.6 hr, $p<0.001$) during loperamide therapy. Loperamide was consistently preferred to the placebo by the patients. Gastrointestinal side-effects (nausea, vomiting, abdominal pain, and distention) were few and comparable during both treatment periods. The ability of loperamide to prolong transit time indicates that it should prove to be particularly useful in patients with intestinal resections or with regional enteritis.

7898 THE DILEMMA OF CROHN'S DISEASE: ILEOSIGMOIDAL FISTULA COMPLICATING CROHN'S DISEASE. (Eng.) Fazio, V. W.; Wilk, P.; Turnbull, R. B., Jr.; Jagelman, D. G. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Dis. Colon Rectum* 20(5):381-386; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7901 A MORPHOMETRIC STUDY OF VENOUS VASCULAR DENSITY OF THE TUNICA MUSCULARIS OF THE ESOPHAGEAL PORTION OF THE ESOPHAGOGASTRIC TRANSITION SEGMENT IN ADULTS. (Por.) Fugimura, I.; de Carvalho, C. A. F. (Dep. de Cirurg., Universidade de Sao Paulo, FMUSP, Brazil). *Arq. Gastroenterol.* 14 (1):17-24; 1977.

Venous vascular bed density was measured in the tunica muscularis of the aboral esophageal region in specimens from 30 cadavers (young adults, 20-30 yr old, who died of portal hypertension). The specimens consisted of 6 cm above and 3 cm below the line of transition (z-line) between the esophagus and stomach; the specimens were treated as a Cartesian coordinate system, with the z-line as the abscissa and the line separating dorsal and ventral halves of the body as the ordinate. The venous density (mm/cm^2) was determined in six levels of ventral and dorsal halves as well as in longitudinal and circular sections (either whole sections or dorsal and ventral half-sections). Longitudinal section densities were generally higher than circular section densities (F=7.74, significant at the 1% level), which suggests a more abundant drainage in the longitudinal direction. Venous density was very slighty higher in the ventral than the dorsal half, and the density decreased very slightly in a caudal to cranial direction.

7902 STUDIES ON RECEPTORS FOR IgG ON EPITHELIAL CELLS OF THE RAT INTESTINE. (Eng.) Borthistle, B. K.; Kubo, R. T.; Brown, W. R.; Grey, H. M. (Veterans Admin. Hosp., Sam Jackson Park, Portland, OR 97207). *J. Immunol.* 119(2):471-476; 1977.

The binding of mouse immunoglobulins to the intestinal epithelium of neonatal rats was investigated. Radioiodinated mouse immunoglobulins of various classes and IgG subclasses, antigen-binding fragments (Fab) and constant fragments (Fc) of IgG, and monomeric and heat-aggregated forms of IgG were instilled into loops of intestine prepared from rats of various ages. The specificity of the radiolabeled immunoglobulin binding was evaluated by competitive inhibition with unlabeled proteins. Monomeric IgG bound specifically to the apical regions of villi in the proximal jejunum. Specific binding progressively decreased from the 12th day of life and could not be demonstrated after about the 21st day of life. Mouse IgA and IgM did not bind specifically. Radioiodinated Fc fragments of IgG bound specifically, whereas radioiodinated Fab fragments did not. Treatment of 14-day-old rats with cortisone acetate caused binding of monomeric IgG to cease prematurely by day 16. Intestinal loops treated with trypsin no longer bound radioiodinated IgG. Heat-aggregated IgG also bound specifically to jejunal epithelium. In contrast to the binding of monomeric immunoglobulin, this binding continued into adulthood and increased in response to cortisone treatment. Aggregated immunoglobulin did not inhibit the binding of monomeric immunoglobulin, but did inhibit the binding of aggregates. These studies (a) confirm the presence of receptors for the Fc region of monomeric IgG on absorptive epithelial cells of the rat jejunum, (b) demonstrate that the receptors disappear at the time when immunoglobulin transport is known to cease, and therefore appear to be critically involved in transport of monomeric IgG, (c) demonstrate that the receptors for monomeric IgG are sensitive to trypsin and disappear prematurely after cortisone treatment, and (d) demonstrate specific binding of aggregated IgG, perhaps by receptor mechanisms different from those involved in the binding of monomeric IgG.

7903 QUALITATIVE AND QUANTITATIVE PRESERVATION OF THE FINE STRUCTURE OF ABSORPTIVE CELLS IN CULTURED BIOPSIES OF HUMAN SMALL-INTESTINE. (Eng.) Ginsel, L. A.; van der Want, J. J. L; Daems, W. T. (Lab. Electron Microscopy, Univ. Leiden, Rijnsburgerweg 10, Leiden, Netherlands). *Cell Tissue Res.* 181(2):143-162; 1977.

The ultrastructure of the absorptive cells in human small intestinal biopsies cultured for 6, 24, and 48 hr was analyzed qualitatively and quantitatively. The cultured absorptive cells were well preserved and had a normal distribution, size, and relative volume of their cell organelles. However, there was a systematic decrease in the apical cell surface and an increase in the number of apical vesicles and tubules after culturing. Since the apical vesicles and tubules are thought to have a function in the transport of cell coat material from the Golgi apparatus to the cell surface, these findings raise the question of whether a delayed transport or extrusion of cell surface material occurs. The diminished relative volume of the mitochondria and the increased signs of autophagy in some poorly preserved absorptive cells are assumed to be an adaptation to less favorable culture conditions.

7904 ULTRASTRUCTURE OF CELL LOSS IN INTESTINAL MUCOSA. (Eng.) Potten, C. S.; Allen, T. D. (Christie Hosp. and Holt Radium Inst., Withington, Manchester M20 9BX, England). *J. Ultrastruct. Res.* 60(2):272-277; 1977.

The process of cell loss from the villi was studied ultrastructurally in the mucosa of the small intestine of PBA-2 mice. The surface of the individual villi was usually marked by numerous longitudinal and horizontal creases. Under electron microscopy, the surface of the tips of the villi varied in appearance from smooth to irregular. Those with an irregular surface often showed evidence of cell separation within and around the clefts. The cell separation was accompanied by changes in the surface morphology due to the production of microvesicles among and above the microvilli. The cell separation extended down between the cells to the basement membrane. The cells became separated from their neighbors when intercellular vacuoles were formed. The separation continued until individual cells were lost, occasionally leaving holes. Relatively normal epithelial cells, as well as occasional dead or dying apoptotic cells and effete goblet cells, were extruded from the mucosa. All three processes occurred at any position on the villus, although most cell loss occurred over the upper third. Cell loss appeared to be more predominant in the early hours of the morning.

7905 ULTRASTRUCTURE OF THE HUMAN PYLORIC GLANDS WITH EMPHASIS ON THE MUCOUS CELL COMPONENT. PART I. (Eng.) Krause, W. J.; Ivey, K. J.; Baskin, W. N.; MacKercher, P. (Sch. Medicine, Univ. Missouri, Columbia, MO 65201). *Acta Anat. (Basel)* 99(1):1-10; 1977.

The ultrastructure of the mucous cell component of the pyloric glands was studied in gastric biopsy specimens from four normal men. The pyloric glands were seen to be simple or branched tubular glands that spiral through the connective tissue of the lamina propria. They were comprised of three cell types: the pyloric gland (mucous) cell, the parietal cell, and endocrine cells. The mucous cell was the most common cell type and was characterized by an abundance of secretory granules. The secretory granules were usually round and varied considerably in diameter. They were membrane-bound and comprised a heterogeneous population. The larger granules contained a light-staining amorphous material and often possessed an area of increased electron density near the limiting membrane of the granule, which gave them a mottled appearance. A smaller, more electron-dense secretory granule was also found in relation both to the Golgi complex and to cell apex. The morphological observations indicate that the mechanism of mucin production by the mucous cells of the human pyloric glands may be similar to that reported in other mucin-secreting cells.

7906 CHANGES OF THE PANCREATIC DUCT SYSTEM ASSOCIATED WITH AGING. (Ger.) Schmitz-Moormann, P.; Hein, J. (Pathologisches Institut der Universitat, Robert-Koch-Str. 5, D-3550 Marburg, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 371(2): 145-152; 1976.

7907 THE EFFECT OF CALORIFICALLY SUBSTANDARD NUTRITION ON THE THIOL GROUPS IN THE CELLULAR NUCLEI HISTORIES OF THE LIVER IN ALBINO RATS OF DIFFERENT AGES. (Rus.) Klimenko, A. I.; Stefanovic A. N. (Inst. Biology, A. M. Gorkii Univ., Kharkov, USSR). *Vopr. Okhr. Materin. Det.* 21(9):15-18; 1976.

7908 THE PYLORUS: CURRENT DATA. (Fre.) Capro J. P.; Dupas, J. L. (Centre Hospitalier Universitaire, place Victor-Pauchet, F 80030 Amiens, France). *Gastroenterol. Clin. Biol.* 1(6/7):593-597; 1977.

7909 FUNCTIONAL-MORPHOLOGICAL CHANGES OF THE GASTROINTESTINAL MUCOSA IN EXPERIMENTAL REPRODUCTION OF HYPOFERRIC CONDITIONS. (Rus.) Ryss, E. S. (I. P. Pavlov First Leningrad Medical Inst., Leningrad, USSR). *Patol. Fiziol. Eksp. Ter.* 1:37-40; 1976.

7910 ELECTRON MICROSCOPIC STUDIES ON THE INNERVATION OF THE STOMACH MUSCLE AND THE INTERSTITIAL CELL OF CAJAL IN THE SMALL INTESTINE OF THE MOUSE AND BAT. (Eng.) Yamamoto, M. (Teikyo Univ Sch. Medicine, Kaga-2-11-1, Itabashi-ku, Tokyo 173, Japan). *Arch. Histol. Jpn.* 40(3):171-201; 1977.

ABSORPTION - EXCRETION - TRANSPORT

7911 INHIBITION OF INTESTINAL UPTAKE OF AMINO ACIDS BY UNCONJUGATED BILE SALT. (Eng.) Burke, V.; Gracey, M.; Thomas, J.; Malajczuk, A. (Princess Margaret Children's Medical Res. Foundation, Perth, Western Australia). *Aust. J. Exp. Biol. Med. Sci.* 54(4):391-402; 1976.

Isolated segments of intestine from Wistar rats were used to study the effect of the unconjugated bile salt sodium deoxycholate (SD) on the intestinal uptake of amino acids. Uptake of radioactive-labeled L-glycine, L-leucine, L-proline, L-tyrosine, L-lysine, L-arginine, and L-ornithine was measured after intestinal tissue was exposed to 0.5 mM SD for 10, 20, 30, 40, or 50 min. The concentrations of L-glycine, L-leucine, L-proline, L-lysine, and L-tyrosine in the intestine were significantly ($p<0.005$, 0.05, 0.02, 0.005, and 0.005, resp.) decreased after exposure to SD. The effect was reversible, except for that of L-lysine, as demonstrated by the normal uptake levels after intestinal segments were rinsed with buffer. It is suggested that the hypoproteinemia observed in patients with bacterial overgrowth in the upper small intestine who have excessive SD in the intestinal lumen may be attributed to interference of amino acid intestinal absorption by the SD.

7912 EFFECT OF GLYCYLGLYCINE ON ABSORPTION FROM HUMAN JEJUNUM OF AN AMINO ACID MIXTURE SIMULATING CASEIN AND A PARTIAL ENZYMIC HYDROLYSATE OF CASEIN CONTAINING SMALL PEPTIDES.

(Eng.) Fairclough, P. D.; Silk, D. B. A.; Clark, M. L.; Matthews, D. M.; Marrs, T. C.; Burston, D.; *et al.* (St. Bartholomew's Hosp., London, England). *Clin. Sci. Mol. Med.* 53(1):27-33; 1977.

Using a jejunal perfusion technique, jejunal absorption of amino acid residues from a partial enzymic hydrolysate of casein in which about 50% of the amino acids existed as small peptides, and also from an equivalent mixture of free amino acids, was determined in normal subjects. The effect of a high concentration of glycylglycine (100 mmol/l) on the absorption of amino acid residues from these preparations was studied to quantify the importance of mucosal uptake of intact peptides during absorption of the partial hydrolysate of casein. Glycylglycine significantly inhibited absorption of several amino acid residues (aspartic acid + asparagine, serine, glutamic acid + glutamine, proline, alanine, phenylalanine, threonine, and isoleucine) from the free amino acid mixture, whereas it significantly inhibited the absorption of only two (serine, glutamic acid + glutamine) from the peptide-containing partial casein hydrolysate. The effect of glycylglycine on absorption of amino acids from the mixture of free amino acids was apparently due to inhibition of amino acid uptake by free glycine liberated from the dipeptide during perfusion. The failure of glycylglycine to cause extensive inhibition of absorption from the partial hydrolysate may be due to glycylglycine being only a weak inhibitor of peptide uptake, but the possibility that some peptides are taken up by a system unavailable to glycylglycine has to be considered.

7913 THE ROLE OF SOME SMALL PEPTIDES IN THE TRANSFER OF AMINO NITROGEN ACROSS THE WALL OF VASCULARLY PERFUSED INTESTINE.

(Eng.) Cheeseman, C. I.; Parsons, D. S. (Dept. Physiology, Univ. Leicester, Leicester LE1 7RH, England). *J. Physiol. (Lond.)* 262(2):459-476; 1976.

The characteristics of the transfer into the vascular bed of L-leucine and glycine from free amino acids or peptides were investigated in the intestinal lumen of *Rana pipiens*. Over the concentration range 0.5-10 mM, the transfer of L-leucine was little affected by the presence of equimolar concentrations of glycine, but glycine transfer was greatly inhibited by the presence of L-leucine. With glycyl-L-leucine in the intestinal lumen, the rate of transfer of glycine into the vascular bed was much greater than from the mixture of the two amino acids and was equal to that of the L-leucine. From L-leucylglycine, the rates of transfer of leucine and of glycine were also higher than from the mixture of the two amino acids, but the rate of glycine transfer was lower than that of leucine. There was no evidence of the presence of the dipeptides in the effluent from the portal vein. When glycyl-L-leucine was added to the lumen in the presence of 10 mM concentrations of the free amino acids, additional amounts of L-leucine and of glycine were transferred in approximately equimolar quantities into the vascular bed. This additional transfer exhibited saturation with respect to concentration of peptide in the intestinal lumen. An additional transfer of amino acids was also found when L-leucyl-glycine was added to the lumen in the presence of saturating concentrations of the two amino acids. The presence of the dipeptides in the intestinal lumen had little effect on the transfer of free amino acids from the lumen into the vascular bed. Although the transfer of free amino acids from the lumen into the vascular bed was significantly, but not completely, abolished when the Na in the intestinal lumen was replaced by K, the transfer of the amino acids from the dipeptides was little affected. The findings are discussed in relation to the view that the dipeptides are transported into the mucosal epithelium by a process that is distinct from those promoting uptake of the individual amino acids. Being completely hydrolyzed, there is no evidence for an accumulative uptake of the peptides; this may be related to the fact that the peptide uptake occurs in the absence of Na in the intestinal lumen.

7914 STUDIES ON KALLIKREINS. IV. ENHANCEMENT OF VALINE TRANSPORT ACROSS THE RAT SMALL INTESTINE.

(Eng.) Moriwaki, C.; Fujimori, H.; Moriya, H.; Kiruki, K. (Lab. Physiological Chemistry, Science Univ. Tokyo, Ichigaya Funagawaracho, Shinjuku-ku, Tokyo, Japan). *Chem. Pharm. Bull.* 25(6):1174-1178; 1977.

The effect of a highly purified hog pancreatic kallikrein and of synthetic bradykinin on the transport of valine across the rat small intestine was examined by an *in vitro* experiment with the sac of inverted jejunum and by an *in situ* mesenteric perfusion experiment. The flow of valine from the mucosal to the serosal side of everted intestine was stimulated significantly ($p<0.01$) by the addition of kallikrein (0.1 KU/ml), to the mucosal fluid while bradykinin was effective only by its addition to the serosal fluid. In a perfusion experiment, valine transport into the vascular system was enhanced significantly by the intraintestinal administration of 0.02-20 KU of kallikrein. The maximum effect was obtained with 2 KU, and the absorption of valine was 1.9 times larger than that of the control. Bradykinin infusion into the mesenteric perfusion system in concentrations of 1.0-100 nM also increased the transport of valine. A bell-shaped dose-response curve, in which the maximum enhancement was achieved with 1 nM of bradykinin, was obtained similar to the case of kallikrein. This effect of kallikrein appeared soon after its administration into the intestinal lumen and usually lasted about 30 min under the present experimental conditions.

7915 KINETICS OF ILEAL TRANSPORT OF BILE ACID AFTER JEJUNECTOMY.

(Eng.) Tilson, M. D.; Hettena, A. J.; Wright, H. K. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *J. Surg. Res.* 22(6):611-615; 1977.

The kinetics of taurocholate transport were studied in ileal remnants after jejunectomy in male Sprague-Dawley rats. Test segments of ileum were perfused with aqueous solutions of 0.9% NaCl and 0.1% inulin with consecutively increasing concentrations of taurocholic acid (0, 10, 30, 100, and 300 μmol/l). There was a significant increase over the control in the mean flux rate for taurocholate in the ileal remnant at a perfusate concentration of 10 μM (187 ± 7 versus 161 ± 10 pM/cm/min, $p<0.05$). It was calculated that there was no difference in passive transport or in the permeability coefficient between the control and the experimental ileum. Thus, the increase in ileal bile acid transport is attributed to increased active transport. The data are consistent with the hypothesis that the affinity of the carrier for taurocholate is increased after jejunectomy.

7916 EFFECT OF ACUTE ETHANOL INGESTION ON FAT ABSORPTION.

(Eng.) Boquillon, M. (Sciences Mirande, Campus Universitaire, 21 000 Dijon, France). *Lipids* 11(12):848-852; 1976.

The effects of acute ethanol administration on fat absorption, on lymph lipid output, and on lymph fat particle size were investigated in rats after lipid feeding, and the effects of ethanol on lipid transit time were examined. A test meal (300 mg casein, 600 mg sucrose, 100 mg corn oil, and a tracer dose of 9,10-^{3}H-oleic acid) was given to fasting adult rats with intestinal lymph fistulas. The animals received either ethanol (3.2 g/kg) or water (2.5 ml) with the meal. Ethanol temporarily delayed the removal of lipid radioactivity from the stomachs. More than 25% of radioactivity fed remained 8 hr after feeding, whereas in control rats, less than 10% of lipid radioactivity fed remained 6 hr after feeding. In controls and ethanol-treated rats, the amounts of exogenous lipids in the intestinal lumen and mucosa were low and similar. Quantities of endogenous and exogenous lipids found in the lymph collected during the 24 hr after feeding were similar in the two groups, but the fat absorption peak was found after 6 hr in alcoholic rats and before 6 hr in controls. This delay was probably due to the retention of lipids in the stomach. More of the exogenous lipid was always transported by small particles moving in the region of α_1 globulins in cellulose acetate electrophoresis than by larger particles remaining at the origin. This proportion was enhanced in the ethanol-treated animals. The larger fat particles were richer in endogenous fatty acids in alcohol-treated rats than in controls. The results indicate that large doses of ethanol delay fat absorption. Ethanol ingestion also seems to increase the exogenous fat transport in lymph as small fat particles.

7917 QUANTITATIVE AND VISUALIZATION STUDIES OF THE TRANSPORT OF RAT AND BOVINE IgG AND FERRITIN ACROSS THE SEGMENTS OF THE SMALL INTESTINE OF THE SUCKLING RAT.

(Eng.) Hemmings, W. A.; Williams, E. W. (Dept. Zoology, Univ. Coll. North Wales, Bangor, Gwynedd, Wales). *Proc. R. Soc. Lond.* [*Biol.*] 197(1129):425-440; 1977.

The quantitative uptake of a homologous protein, rat IgG, and a heterologous protein, horse spleen ferritin (HSF), from the duodenum, ileum, and jejunum of 14-day-old rats was studied. The histological distribution of ^{125}I-labeled IgG and ^{131}I-labeled HSF was observed by electron microscopy. The injection mixtures contained equal activities of both isotopes and a total protein concentration of 2.4 mg/ml. A volume of 0.2 ml was injected into ileum, 0.15 ml into the duodenum and jejunum; all three sections were separated by ligatures. Radioactivity was measured in the injected portion of the gut, the gut washings, and the whole animal. Both duodenum and ileum actively transported rat IgG and HSF. The selective ratio for IgG compared to HSF was slightly greater in the duodenum. Proteolysis occurred in both segments, but there was a greater breakdown of proteins in the ileum. A high percentage of radioactivity in the whole anima was still protein-bound. The quantitative results were supported by electron microscopy studies. HSF was transported across the duodenal and ileal cells in quantity, and both proteins were distributed throughout the cell cytoplasm. It is concluded tha different mechanisms of protein transport operate in the duodenum and ileum of the young rat.

7918 POTASSIUM TRANSPORT ACROSS THE DISTAL COLON IN MAN.

(Eng.) Salas-Coll, C. A.; Kermode, J. C.; Edmonds, C. J. (Clinical Res. Center, Watford Rd., Harrow, Middlesex HA1 3UJ, England). *Clin. Sci. Mol. Med.* 51(8):287-296; 1976

The mechanism of potassium transport across human distal colon was investigated in 22 subjects without bowel disease, using a dialysis method in conjunction with measurements of the transepithelial potential difference (PD). Whether potassium was absorbed or secreted depended on its initial concentration in the lumen. The potassium net flux was approximately zero when the luminal potassium concentration was between 30 and 50 mM. The potassium secretion rate was not significantly affected by the sodium absorption rate, by the luminal sodium concentration, or by the osmolality of the luminal solution. The potassium secretion rate was increased by partial substitution of other cations for sodium, in the descending order Li>NH_4>Rb>Na. Potassium concentration increased an average of greater than 80 mM when lithium was in the lumen. The observed transepithelial PD was inadequate to account for the intraluminal potassium concentrations attained, the discrepancy being most marked when ammonium or lithium was in the lumen. It is suggested that some potassium is secreted by the epithelial cells, and this component of the total potassium flux into the lumen is increased when rubidium, ammonium, or lithium is substituted for sodium.

7919 CALCIUM-PROSTAGLANDIN AGGREGATION AND ITS EFFECT ON PROSTAGLANDIN UPTAKE BY ISOLATED RABBIT INTESTINE. (Eng.) Bikhazi, A. B.; Nadir, N. S.; Hajjar, J. J. (Sch. Pharmacy, American Univ. Beirut, Beirut, Lebanon). *J. Pharm. Sci.* 66(9): 1308-1312; 1977.

The interaction between calcium and prostaglandins was studied in the rabbit, and the data were correlated to intestinal prostaglandin uptake. A quantitative estimate of the role of calcium ions on the lipid-water partition coefficients of prostaglandin E_1 and dinoprost suggested the possibility that prostaglandin molecules and calcium ions aggregate in a 14:1 ratio to produce a lipid-soluble complex. The aggregation was postulated to be a characteristic of prostaglandin molecules as compared to simple fatty acids (e.g., 1-octanoic acid) which, in the presence of calcium, behaved differently than the prostaglandins. The uptake of prostaglandins by the mucosal surface of the rabbit intestine increased in the presence of calcium. At 25 mM calcium, prostaglandin E_1 was transported at approximately twice the rate as in the system containing no calcium. The uptake rate of dinoprost was estimated to be three times faster in the presence of 10 mM calcium than in the absence of calcium. Therefore, it is proposed that a carrier-mediated diffusion process, for both the prostaglandin molecules and calcium ions, occurs in the uptake mechanism. Diffusion coefficients ranging from 0.48×10^{-5} to 7.19×10^{-5} cm^2/sec and permeability coefficients ranging from 1.04×10^{-2} to 15.6×10^{-2} cm/sec were estimated for all systems studied.

7920 INTERRELATIONSHIP BETWEEN SUGAR-EVOKED INCREASES IN TRANSMURAL POTENTIAL DIFFERENCE AND SUGAR INFLUXES ACROSS THE MUCOSAL BORDER IN THE SMALL INTESTINE. (Eng.) Hoshi, T.; Suzuki, Y.; Kusachi, T.; Igarashi, Y. (Tohoku Univ. Sch. Medicine, Sendai 980, Japan). *Tohoku J. Exp. Med.* 119(3):201-209; 1976.

The relationship between changes in the transmural potential induced by actively transported sugars (ΔPD) and influxes of the sugars (J_s) was investigated in the isolated guinea pig small intestine. When the electrical conductivity of the medium remained constant, ΔPD and J_s were closely correlated; both showed very similar patterns of regional difference along the intestine, and the values of the half saturation concentration (K_m) for a sugar estimated from electrical and flux measurements were nearly identical. No such correlation was observed when medium conductivity varied. However, a simple correction of the sizes of ΔPD for medium conductivity restored a close parallel between ΔPD and J_s. The sugar-induced increase in Na^+ flux estimated from the increase in short-circuit current varied in parallel with J_s, regardless of the medium conductivity, and a fixed stoichiometric relation (approximately one-to-one coupling) was seen between Na^+ and sugar fluxes. It is concluded that the dominant factor affecting the interrelation between ΔPD and J_s is the resistance of the paracellular shunt, which is directly proportional to medium electrical conductivity.

7921 EFFECT OF INDOMETHACIN ON INTESTINAL WATER TRANSPORT IN SALMONELLA-INFECTED RHESUS MONKEYS. (Eng.) Giannella, R. A.; Rout, W. R.; Formal, S. B. (Veterans Admin. Hosp., Lexington, KY 40506). *Infect. Immun.* 17(1):136-139; 1977.

Experiments were carried out in rhesus monkeys to determine whether indomethacin can inhibit salmonella-induced intestinal secretion when administered after both infection and net intestinal secretion are well established. Indomethacin (10 mg/kg, i.v.), caused a striking enhancement of net intestinal water transport in the jejunum, ileum, and colon of salmonella-infected monkeys. These effects occurred promptly and were of sufficient magnitude in the ileum and colon to cause a reversal in the direction of net transport from net secretion to net absorption. Indomethacin also enhanced net water transport in the jejunum, ileum, and colon of normal animals. These data show that indomethacin markedly enhances net intestinal water transport in both the small and large intestines of salmonella-infected monkeys, even when administered after salmonella infection and intestinal secretion are well established. Similar enhancement also occurs in the normal intestine.

MOTILITY

7935 NOVEL TELEMETRIC SYSTEM FOR EXTRALUMINAL MEASUREMENT OF GASTROINTESTINAL MOTILITY. (Eng.) Shearin, N. L.; Pfeiffer, C. J.; Kilam, S. (Faculty Medicine, Memorial Univ. Newfoundland, St. John's, Newfoundland A1C 5S7, Canada). *J. Appl. Physiol.* 41(3):425-428; 1976.

A frequency-modulated, telemetric system with a transducer sensitive to variation in distance between two points was developed and used to measure *in vivo* small intestinal motor function in unanesthetized dogs. The construction of the system and one application of it to the study of gastrointestinal motility is described. Data were recorded after fasting, 1 hr after feeding a standardized meat meal, and after i.v. injections of pentagastrin (10.0 μg/kg). A significant increase in motility was seen after pentagastrin injections and feeding, as compared to the motility pattern seen in a fasting animal. The telemetric system was proven to be adequate for *in vivo* measurement of motility of the gastrointestinal tract.

7936 EFFECTS OF SOMATOSTATIN AND HUMAN GASTRIN I ON THE LOWER ESOPHAGEAL SPHINCTER IN MAN. (Eng.) Heil, T.; Mattes, P.; Raptis, S. (Departement fur Chirurgie, Universitat Ulm, Postfach 3880, D-7900 Ulm/Donau, W. Germany). *Digestion* 15(6):461-468; 1977.

The influence of somatostatin and physiological concentrations of gastrin on the lower esophageal sphincter was investigated in 10 metabolically healthy volunteers and in one patient with the Zollinger-Ellison syndrome. Only unphysiologically high serum concentrations of gastrin (300-600 pg/ml) during exogenous gastrin (0.6 μg/kg/hr) administration produced a rise in pressure in the lower esophageal sphincter, while somatostatin (250 μg as an i.v. bolus, followed by 250 μg/hr for 1 hr) had no effect on the lower esophageal sphincter pressure, nor was it able to inhibit the pharmacological effect of exogenous gastrin administration. The results demonstrate that normal levels of serum gastrin do not seem to have much effect on resting lower esophageal sphincter pressure, nor does somatostatin.

7937 PERISTALSIS IN SMOOTH MUSCLE ESOPHAGUS AFTER TRANSECTION AND BOLUS DEVIATION.

(Eng.) Janssens, J.; De Wever, I.; Vantrappen, G.; Hellemans, J. (Laboratorium voor Gastrointestinale Physiopathologie, Univ. Leuven, Z.Z. St. Rafael, B-3000 Leuven, Belgium). *Gastroenterology* 71(6): 1004-1009; 1976.

The importance of the continuity of the muscle coat and of the presence of an intraluminal bolus for the peristaltic performance of the esophagus was studied in the Rhesus monkey. Transection and re-anastomosis with muscle-to-muscle contact in the striated muscle part of the esophagus did not interfere with the progression of primary peristaltic contractions. However, when the transection with re-anastomosis was performed in the smooth muscle part of the gullet, the peristaltic progression of the deglutitive contraction waves in the segment below the transection was affected. After deviation of the swallowed bolus either in the cervical striated esophagus or in the smooth muscle part of the thoracic esophagus, primary peristaltic contractions progressed over the entire length of the gullet; however, in the thoracic esophagus, the presence of a bolus facilitated the peristaltic progression of primary waves. These studies indicate that the extramural vagal innervation is involved in secondary peristaltic contractions of the smooth muscle esophagus.

7938 DYNAMICS OF THE PARTIAL RESTORATION OF SLOW-WAVE FREQUENCY OF THE DUODENUM BELOW TRANSECTION (ELECTROPHYSIOLOGICAL AND MORPHOLOGICAL INVESTIGATIONS).

(Eng.) Atanassova, E.; Jurukova, Z.; Kortezova, N. (Inst. Physiology, Bulgarian Acad. Sciences, Sofia, Bulgaria). *Acta Physiol. Pharmacol. Bulg.* 2(2):25-34; 1976.

The role of the nervous system in the restoration of the slow wave frequency of the duodenal segment below an anastomosis was studied in dogs. The proximal duodenum was transected, and this was followed by end-to-end anastomosis. The electrical activity of the duodenal wall of both segments was recorded. On the background of decreased slow wave frequency below the section, single slow waves were observed, with duration similar to that of the slow waves above the section. After surgery, their number increased, small groups of such waves appearing during and after spike activity. In some experiments from the end of the first month to the sixth month after surgery, the slow wave frequency below the section approached the slow wave rhythm above the section, as evidenced by the histograms. This was temporary and was partly eliminated by cholinergic and alpha- and beta-adrenergic antagonists. This phenomenon was also observed in definitively separated distal segments of the duodenum. Histological examination of specimens of the intestinal wall taken from the area of anastomosis showed single smooth muscle cells among the granulation tissue, filling the gap between the wound edges on the third day; on the sixth day, the number of these cells increased, and on the ninth and twelfth days, they formed small groups. From the end of the first month to the sixth month, small sheaves of smooth muscle cells were observed in the cicatricial tissue. It is concluded that the intrinsic nervous system keeps the slow wave frequency below the duodenal transection at a higher level than the smooth muscle cell regeneration might ensure.

7939 A POSSIBLE ROLE OF PROSTAGLANDINS IN GUINEA-PIG ISOLATED ILEUM CONTRACTIONS TO SEROTONIN.

(Eng.) Famaey, J. P.; Fontaine, J.; Seaman, I.; Reuse, J. (Sch. Medicine, Univ. Brussels, 115, boulevard de Waterloo, 1000 Brussels, Belgium). *Prostaglandins* 14(1):119-124; 1977.

Nine nonsteroidal anti-inflammatory drugs were tested for their effect on serotonin-induced contractions in the isolated guinea pig ileum. These drugs (flufenamic acid, mefenamic acid, bufexamac, niflumic acid, indomethacin, clopirac, ibuprofen, phenylbutazone, and alclofenac at 2.5-40, 2.5-40, 5-10, 10-40, 10-40, 40, 40, 100-200, and 200 μg/ml, resp.) inhibited the ileal contractions in a dose-related manner. This inhibition was totally reversible by washing out the drugs. The inhibition was also reversed by adding a small quantity of prostaglandin E_1 (2.5 ng/ml) to the bath. It is concluded that prostaglandins exert both specific and nonspecific effects on ileal contraction.

7940 INHIBITION OF GASTRIC ELECTRICAL AND MECHANICAL ACTIVITY BY INTRADUODENAL AGENTS IN PIGS AND THE EFFECTS OF VAGOTOMY.

(Eng.) Roze, C.; Couturier, D.; Chariot, J.; Debray, C. (Hopital Bichat, 170, boulevard Ney, F-75877 Paris Cedex 18, France). *Digestion* 15(6):526-539; 1977.

The inhibitory effects of acid, hyperosmolar glucose, fat, and amino acids on gastric electrical and motor activity were compared after a normal meal, and the effects of truncal vagotomy on these inhibitory effects were assessed. Miniature pigs were chronically implanted with gastric electrodes, with strain gauge devices allowing the measurement of circular contractions in the antrum and body of the stomach, and with a duodenal catheter through which duodenal infusions were administered. Inhibition of gastric motility by intraduodenal agents was measured before and after truncal vagotomy in conscious animals 20 min after a normal meal. HCl (75 mEq/l), glucose (100 g/l), olive oil (10%, pH 7), amino acids, and saline were infused intraduodenally at a rate of 10 ml/min (4 min). Before vagotomy, motor activity during the first 5 min was inhibited 50-80% with respect to basal levels. The duration of inhibition was shorter with HCl than with glucose and fat. Amino acid infusion had very little effect, and saline had no effect. Inhibition was similar in the antrum and gastric body. After vagotomy, the inhibitory effect of HCl was reduced from 80% to 20% in the antrum and was completely suppressed in the gastric body. The inhibitory effects of glucose and olive oil were completely suppressed. The results stress the importance of a normal vagal supply to the duodenum and stomach in the inhibition of gastric motility induced by agents in the duodenum.

7956 RELEASE OF VASOACTIVE INTESTINAL PEPTIDE (VIP) BY INTRALUMINAL OSMOTIC STIMULI.

(Eng.) Ebeid, A. M.; Soeters, P. B.; Murray, P.; Fischer, J. F. (Dept. Surgery, Massachusetts General Hosp., Boston, MA 02114). *J. Surg. Res.* 23(1):25-30; 1977.

Blood levels of vasoactive intestinal peptide (VIP) and insulin were measured in dogs after intraluminal osmotic stimulation of the duodenum. Two methods were used to infuse 300 ml of 6% or 3% hypertonic saline solution: (1) the animals were laparotomized, and the solution was infused directly into duodenum and (2) a jejunal loop with an intact blood supply was transposed anterior to the duodenum, where one end was anastomosed to the duodenum in end-to-side fashion and one end was secured s.c.; the solution was infused extraabdominally in the "closed" animal. VIP and insulin were measured by radioimmunoassay in blood drawn 0, 3, 5, 10, 20, 40, and 60 min postinfusion. VIP was significantly elevated ($p<0.05$) at 5 and 10 min after the infusion of 6% saline. The response to 3% saline was less marked, but it was significant ($p<0.02$) at 5, 10, and 20 min. The rise in VIP levels was accompanied by significant rise in insulin, but only after the 3% saline infusion. The results were similar in the laparotomized and "closed" animals. It was concluded that VIP is an insulinotropic hormone.

7957 ROLE OF CYCLIC ADENOSINE MONOPHOSPHATE IN THE REGULATION OF THE SECRETORY FUNCTION OF THE DIGESTIVE GLANDS (LITERATURE SURVEY).

Stomach

7959 MORPHOLOGICAL AND PHARMACOLOGICAL STUDIES OF THE PARIETAL CELLS OF THE STOMACH IN THE DOG DURING PERIODS OF MAXIMAL ACID OUTPUT AND AFTER THE GASTRIC SECRETORY INHIBITOR UK-9040.

(Eng.) Hamer, D. B.; Price, A. B.; Baron, J. H. (St. Mary's Hosp., London W.2, England). *Gut* 18(2):91-98; 1977.

The effects of UK-9040, a derivative of the antihistamine triprolidine, on gastric secretion and parietal cell structure were studied in dogs. UK-9040 reduced gastric acid, pepsin, and volume output in response to food, insulin, histamine, N-methyl histamine, and pentagastrin. Doses of 6-36 mg/kg administered p.o. 4-5 hr before the secretagogues produced a dose-dependant and up to 100% inhibition in the outputs of innervated gastric fistula and denervated Heidenhain pouch. Inhibition was still present 24 hr after the administration of UK-9040 but was absent at 48 hr. Blood pressure and pulse rate were not affected. The normal ultrastructural responses to gastric secretory stimulation were arrested. UK-9040 showed no cumulative effect, tolerance did not occur, and after withdrawal of the drug, the physiological and morphological gastric responses of the parietal cells rapidly returned to normal. Although UK-9040 has not been developed for use in humans because of cardiotoxicity, it is hoped that other inhibitory drugs of this series might provide the basis for an approach to hypersecretory diathesis.

7960 THE EPITHELIUM IN HEALING EXPERIMENTAL STANDARD LESIONS IN THE GASTRIC MUCOSA OF THE RAT: A LIGHT MICROSCOPICAL AND SCANNING ELECTRON MICROSCOPICAL STUDY.

(Eng.) Schroeder, J. J. M.; James, J.; Muller, J. H.; Everts, V.; Klopper, P. J. (Histological Lab., Univ. Amsterdam, le Const. Huygenstraat 20, Amsterdam, Netherlands). *Digestion* 15(5):397-410; 1977.

The movement of the advancing sheet of epithelial cells streaming from the border region into the wound bed of standardized defects during the healing process was studied in the rat glandular stomach mucosa, using light and scanning electron microscopy. A very high synthetic activity of mucus in gastric lining cells of the border region (with a typical shift in its reaction product towards a more acidly reacting product showing metachromasia with toluidine blue) was observed histochemically, together with a loss of characteristic features of glandular cells in the border region with an increase in mitotic activity. The scanning electron microscope (SEM) images enabled a detailed analysis of the advancing epithelial front in its relation to the border regions. Considerable local differences were noted in the moving pattern of the migrating epithelium, possibly in relation to the nature of the base on which it has to move. The lesion (3 mm in diameter) usually closed after 10 days; in some instances, however, small epithelial defects were later found that could easily be traced with the SEM.

7961 CYCLIC ADENOSINE MONOPHOSPHATE AND HUMAN GASTRIC ACID SECRETION. (Eng.) Bower, R. H.; Sode, J.; Lipshutz, W. H. (Naval Regional Medical Center, San Diego, CA 92134). *Am. J. Dig. Dis.* 22 (8):705-711; 1977.

Cyclic AMP (cAMP) levels were determined by radioimmunoassay in the gastric juice, plasma, and urine of 27 subjects undergoing routine gastric analysis under maximum stimulation with betazole (1.5 mg/kg) or pentagastrin (6 μg/kg). No increase in the concentration of cAMP was noted in gastric juice, plasma, or urine following either betazole or pentagastrin stimulation. Betazole-stimulated human gastric acid secretion was associated with an increased cAMP output into the gastric juice ($p<0.05$). There was no change in cAMP output following pentagastrin stimulation. The peak acid output produced by pentagastrin and betazole was similar. The lack of increase in cAMP concentration supports the concept that cAMP is not a primary mediator in the stimulation of gastric acid secretion by betazole or pentagastrin in the human. The physiologic significance of the increase in cAMP output following betazole stimulation remains unresolved.

7962 THE EFFECT OF ANAESTHESIA ON THE INHIBITION OF PENTAGASTRIN-EVOKED GASTRIC ACID SECRETION INDUCED BY ATROPINE IN THE RAT. (Eng.) Hedges, A. R.; Parsons, M. E. (Guy's Hosp. Medical Sch., London Bridge, London SE1 9RT, England). *J. Physiol. (Lond.)* 267(1):181-194; 1977.

The effect of anesthesia on the inhibition of pentagastrin-stimulated gastric acid secretion induced by atropine was studied in rats with gastric fistulas or Heidenhain pouches. In the anesthetized vagally intact rat with a perfused gastric lumen, atropine (25 μg/kg, s.c.) inhibited maximal pentagastrin-evoked gastric acid secretion by a mean of 60.2 ± 18.5%. Submaximal pentagastrin-stimulated secretion was inhibited to a similar extent. In anesthetized vagotomized rats with a perfused gastric lumen, atropine (25 μg/kg-1.6 mg/kg, s.c.) had no inhibitory effect on maximal pentagastrin-evoked gastric acid secretion. In the conscious fistula rat, atropine (400 μg/kg) totally abolished the basal and maximal gastric acid secretion evoked by pentagastrin. In the anesthetized chronic fistula rat, doses of up to 1.6 mg/kg atropine produced a maximum inhibition of 70.2% of maximal pentagastrin-evoked gastric acid secretion. Vagotomy did not affect the response to atropine. In the conscious Heidenhain pouch rat, up to 1.6 mg/kg atropine produced a maximum inhibition of 70.9% of maximal pentagastrin-evoked gastric acid secretion. Anesthesia and/or vagotomy did not affect the response to atropine. The results indicate that anesthesia reduces the effectiveness of atropine as an inhibitor of pentagastrin-induced secretion in fistula rats but not in Heidenhain pouch rats.

7963 EFFECT OF CIMETIDINE ON PENTAGASTRIN-STIMULATED GASTRIC SECRETION IN HEALTHY MAN. (Eng.) Aadland, E.; Berstad, A.; Semb, L. S. (Aker Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 12(4):501-506; 1977.

The kinetics of the inhibition of pentagastrin-stimulated gastric acid and pepsin secretion by cimetidine were studied in three healthy subjects by establishing dose-response curves for both pentagastrin and cimetidine. In one series of experiments, increasing doses of cimetidine were tested on a constant background stimulation with 0.15 μg/kg/hr of pentagastrin. In another series of experiments, increasing doses of pentagastrin were given either alone or in combination with a fixed dose of cimetidine (1.2 mg/kg/hr). Pentagastrin and cimetidine were given as continuous i.v. infusions, the various doses were tested on separate days. The inhibition of acid output in response to pentagastrin stimulation increased almost linearly with the log dose of cimetidine. Fifty percent inhibition of the response to 0.15 μg/kg/hr of pentagastrin was achieved with 0.6 mg/kg/hr of cimetidine. Cimetidine at 2.4 mg/kg/hr gave an average of 90% inhibition. The inhibition caused by cimetidine decreased to a minimum of 57% and could not be overcome by increasing the doses of pentagastrin. The results suggest a mixture of competitive and noncompetitive interaction. The effect of cimetidine on pepsin secretion was less regular. Generally, pepsin output was less inhibited than acid output.

7964 LOCALIZATION OF HISTAMINE AND HISTAMINE H_2-RECEPTOR ANTAGONISTS IN THE GASTRIC MUCOSA. (Eng.) Cross, S. A. M. (Smith Kline & French Lab. Ltd., Welwyn Garden City, Hertfordshire, England). *Histochem. J.* 9(5):619-644; 1977.

Histochemical studies were done on the gastric mucosa of rats and one dog in relation to acid secretion, histamine, and the H_2-receptor antagonists. Acid secretion by the parietal cell is stimulated by histamine and inhibited by the histamine H_2-receptor antagonist. Whole-body autoradiography showed that radioactivity from ^{14}C-histamine was localized in the artery walls and in the muscularis mucosae, but that the level in the fundic mucosa was the same as that in the blood. When the H_2-receptor antagonists burimamide (33-150 mg/kg, 11 rats), metiamide (10-150 mg/kg), and cimetidine (30 mg/kg) were labeled with ^{35}S, ^{14}C, or ^{3}H and administered p.o. to rats, whole-body autoradiography showed that stomach was predominately labeled in the glandular mucosa 5-120 min after administration. Microautoradiography in the rat and dog after the i.v. injection of ^{3}H-metiamide (1 mCi/150 g; 55 mg/kg) or ^{3}H-cimetidine (1 mCi/150 g; 66 mg/kg) demonstrated an uptake in the parietal cell cytoplasm that was three to four times greater than that found in adjacent peptic cells or in areas of the muscularis mucosa. The preferential labeling persisted at a low level up to 6 hr after injection. However, the mast cells were labeled in the rats, but not in the dog. The localization of radioactivity from the H_2-receptor antagonists in the parietal cell cytoplasm correlates well with their pharmacological activity in preventing acid secretion from this cell.

7965 EVIDENCE FOR ANTRAL INHIBITION OF PENTAGASTRIN FROM EXPERIMENTS USING MUCOSAL COOLING. (Eng.) Kondo, T.; Magee, D. F. (Creighton Univ. Sch. Medicine, 2500 California St., Omaha, NB 68178). *J. Physiol.* 270(1):37-50; 1977.

The effect of a temperature change in the pyloric and Heidenhain pouches (HP) on acid and pepsin secretion from both the HP and the main stomach of dogs was studied. In response to pentagastrin (PG), the acid secretion of the fundic mucosa in HP gradually lessened as the pouch mucosa was cooled to 5 C. When a cooled HP in dogs receiving PG was warmed to 37 C, acid and pepsin secretion from the main stomach was depressed. Change from a warm to a cool temperature produced no obvious effect. In animals receiving PG continuously, but not in those receiving histamine, lowering the temperature in a fully innervated antral pouch or the application of local anesthetics to its mucosa increased acid and pepsin secretion from the main stomach. This effect could be abolished readily by ganglionic and β-adrenergic blockade, but not by a bilateral vagal block in the neck, which suggests the existence of a sympathetically mediated inhibitory mechanism of pyloric origin. The effect of indirect vagal stimulation, using 2-deoxy-D-glucose, on secretion from the main stomach was augmented by pyloric antral local anesthesia and depressed by antral cooling. It is concluded that cooling, local anesthesia, or β-adrenergic blocking agents do not interfere with, or modify, one another with respect to acid and pepsin secretion.

7966 EFFECTS OF TANDAMINE AND PIRANDAMINE, SELECTIVE BLOCKERS OF BIOGENIC AMINE UPTAKE MECHANISMS, ON GASTRIC ACID SECRETION AND ULCER FORMATION IN THE RAT. (Eng.) Lippmann, W.; Seethaler, K. (Ayerst Res. Lab., Box 6115, Montreal, Quebec, Canada H3C 3JI). *Life Sci.* 20(8): 1393-1400; 1977.

The effects of tandamine and pirandamine and various of their structurally-related compounds on gastric acid secretion and ulcer formation were studied in the rat. Tandamine and its structurally-related compounds, but not pirandamine or its structurally-related compound, given i.p. (0.5 ml), inhibited gastric acid secretion and were similar in activity to imipramine (4 mg/kg, p.o.). Like imipramine, tandamine (0.2 ml) was effective when given p.o. None of the compounds examined, administered i.p., were effective in reducing the ulcer formation in 19-hr pylorus-ligated animals, while imipramine was effective. Tandamine, like imipramine, inhibited ulcer formation in 10-hr pylorus-ligated animals and in 19-hr pylorus-ligated animals when given in divided doses. Tandamine and its structurally-related compounds, but not pirandamine or its structurally-related compound, given s.c., prevented reserpine-induced gastric ulceration; imipramine was also effective. Tandamine and imipramine, administered i.p., prevented gastric stress ulceration. The compounds that block the norepinephrine, or in addition the serotonin, uptake mechanism, but not those that block only the serotonin uptake mechanism inhibited the gastric acid secretion and reserpine-induced ulceration. Thus, these latter activities appear to be correlated with the inhibition of the norepinephrine, rather than serotinin, uptake mechanism.

7967 VAGAL INFLUENCE ON GASTRIN AND GASTRIC ACID RESPONSES TO GASTRIC AND INTESTINAL MEALS. (Eng.) Konturek, S. J.; Llanos, O. L.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Physiol.* 232(6):E542-E546; 1977.

To study the vagal influence on gastrin and gastric acid responses to gastric and duodenal meals, five dogs were prepared with a special gastroduodenal cannula that allowed complete separation and selective stimulation of the stomach or the duodenum. The stomach or duodenum was stimulated with a 10% liver extract meal, and serum gastrin levels and acid secretions were determined. Prior administration of atropine sulfate (100 μg/kg/hr) in dogs with intact vagus nerves caused about 80% inhibition of acid secretion during the gastric phase and complete suppression of acid secretion during the intestinal phase. In these tests, atropine strongly suppressed serum gastrin levels during the gastric phase, but failed to inhibit the gastrin response in the intestinal phase. Truncal vagotomy had a weak effect on acid secretion and gastrin release during the gastric phase, but resulted in a pronounced increase in gastric acid secretion and higher levels of gastrin during the intestinal phase. Atropine in vagotomized dogs caused a similar reduction in gastric acid secretion in gastric and intestinal phases, but was more effective in blocking gastrin release in both phases after vagotomy. This study indicates that in the intact dogs, an atropine-sensitive mechanism for gastrin release is confined to the stomach, whereas an atropine-resistant mechanism is located in the intestine. After vagotomy, gastrin release in the gastric or intestinal phase becomes more atropine sensitive, which suggests that the vagus nerves exert an inhibitory influence on local cholinergic mechanisms responsible for the postprandial release of gastrin.

7968 STUDIES ON THE ROLE OF CEPHALIC-VAGAL STIMULATION IN THE ACID SECRETORY RESPONSE TO EATING IN NORMAL HUMAN SUBJECTS. (Eng.) Richardson, C. T.; Walsh, J. H.; Cooper, K. A.; Feldman, M.; Fordtran, J. S. (Univ. Texas Southwestern Medical Sch., Dallas, TX 75235). *J. Clin. Invest.* 60(2): 435-441; 1977.

The importance of cephalic-vagal stimulation in the acid secretory response to eating was studied in nine normal subjects. Cephalic stimulation was induced by a modified sham feeding (MSF) technique, during which subjects chewed and expectorated appetizing food. The response to MSF was compared with that to gastric distention with 600 ml NaCl, glucose, or food. In addition, the extent to which cephalic stimulation augmented acid secretion that had been stimulated simultaneously by these other mechanisms was studied. Cephalic stimulation accounted for approximately one-third of the acid secreted when all mechanisms acted simultaneously (food-distention plus MSF). Within the limits imposed by the maximal secretory capacity, the response to MSF was approximately the same, regardless of whether acid secretion was otherwise unstimulated or was stimulated simultaneously by gastric distention with NaCl, glucose, or food. Gastric distention prolonged the response to cephalic stimulation ($p<0.05$). Since cephalic-vagal stimulation accounts for one-third of the acid secreted when all mechanisms act simultaneously, increased vagal activity secondary to cephalic influences is an important mediator of acid secretion during and after a meal.

7969 GASTRIC MUCINOUS SECRETION UNDER VARIOUS CONDITIONS OF STIMULATION IN HYPOTHYROID DOGS. (Eng.) Kowalewski, K.; Pachkowski, T.; Secord, D. C. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, Alberta T6G 2N8, Canada). *Pharmacology* 15(4):348-358; 1977.

The effect of hypothyroidism on the gastric secretion of mucinous components and of amino acids was studied in dogs. Principal glycoproteins and amino acids of the secretions from Heidenhain pouches were studied in normothyroid and hypothyroid dogs in the resting state, following the injection of pentagastrin (6 μg/kg) or histamine (1 mg/kg) and after feeding. Hypothyroidism was produced by total thyroidectomy and chronic treatment with thiouracil. All samples showed the presence of galactose, glucosamine, galactosamine, fucose, mannose, uronic acid, and sulfate. Galactose and glucosamine were found in equimolar amounts, and the galactose to galactosamine ratio was 2:1; this ratio was not affected significantly by hypothyroidism or by the mode of gastric stimulation. Concentrations of most carbohydrate components studied were higher in normothyroid than in hypothyroid dogs. Concentrations of most amino acids analyzed were also higher in normothyroid than in hypothyroid dogs, following stimulation with secretagogues.

7982 CHRONIC AND ACUTE STUDIES INDICATING ABSENCE OF EXOCRINE PANCREATIC FEEDBACK INHIBITION IN DOGS. (Eng.) Sale, J. K.; Goldberg, D. M.; Fawcett, A. N.; Wormsley, K. G. (Royal Hosp., Sheffield, England). *Digestion* 15(6):540-555; 1977.

Experiments were carried out to determine whether the proposed feedback control of pancreatic enzyme secretion could be demonstrated in dogs. The chronic administration of raw soybean flour (24% of diet) containing active trypsin inhibitor reduced the pancreatic output of trypsin and chymotrypsin in response to cholecystokinin. Dogs stimulated by a meat meal showed no consistent alteration in the output of trypsin and chymotrypsin when given additional duodenal infusions of trypsin and chymotrypsin, canine pancreatic juice, or ovalbumin trypsin inhibitor. When the pancreas was stimulated by the intraduodenal infusion of amino acids in two dogs, no consistent change was seen when trypsin alone, trypsin together with trypsin inhibitors, or trypsin together with canine pancreatic juice was infused concurrently into the duodenum. These results indicate that feedback control of pancreatic enzyme secretion does not exist in dogs.

7983 INTERACTION OF SYNTHETIC 10-TYROSYL ANALOGUES OF SECRETIN WITH HORMONE RECEPTORS ON PANCREATIC ACINAR CELLS. (Eng.) Gardner, J. D.; Conlon, T. P.; Beyerman, H. C.; van Zon, A. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, NIH, Bethesda, MD 20014). *Gastroenterology* 73(1): 52-56; 1977.

To determine the structural requirements for various peptides to interact with hormone receptors, four synthetic secretin analogs (10-tyrosine; 4-alanine, 10-tyrosine; 3-glutamine, 10-tyrosine; and 3-glutamic acid, 10-tyrosine) were tested for their ability to interact with hormone receptors on dispersed acinar cells from guinea pig pancreas. [10-Tyrosine]secretin inhibited the binding of ^{125}I vasoactive intestinal peptide (VIP) to the same extent as native secretin. Thus, substituting tyrosine for leucine in position 10 of porcine secretin makes the peptide structurally more like porcine VIP, but it does not make the peptide more VIP-like in terms of its ability to interact with the high-affinity VIP receptor. Although VIP has alanine in position 4, substituting alanine for glycine in position 4 of [10-tyrosine]secretin made the peptide functionally less VIP-like in that it reduced the ability of the peptide to inhibit ^{125}I VIP binding. Each of the four analogs interacted with the high-affinity secretin receptor to increase cellular accumulation of cyclic AMP. The 10-tyrosine analog was approximately one-tenth as potent as secretin. In [10-tyrosine]secretin, adding one methyl group to the side chain of the amino acid in position 4 (replacing glycine by alanine) or interposing a methyl group in the acidic side chain of the residue in position 3 (replacing aspartic acid by glutamic acid) reduced the apparent affinity of the peptide for the high-affinity secretin receptor by 15- or 40-fold, resp. These results illustrate how changes in the amino-terminal region of secretin, which in terms of peptide structure might appear to be relatively trivial, can produce substantial changes in the apparent affinity of secretin for its receptors.

7984 INDEPENDENT SECRETION OF DIFFERENT DIGESTIVE ENZYMES BY THE PANCREAS. (Eng.) Rothman, S. S. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Am. J. Physiol.* 231(6): 1847-1851; 1976.

Pancreatic amylase, chymotrypsinogen, trypsinogen, and total protein levels were determined in the secretion collected from the cannulated duct of anesthetized rabbits during the perfusion of the upper duodenum with a balanced salt solution with or without 5 mM glucose. While glucose did not increase overall digestive enzyme secretion, it did change the proportions of the enzymes in secretion. In addition, non-0,0 intercepts were observed when the output of one enzyme was plotted against that of another (an enzyme-pair plot). There were also changes in the variance of the slope and intercept of enzyme-pair plots and an increase in the variance around the slope of an enzyme-pair plot, concurrent with a decrease in the variance around the slope of a plot for another enzyme pair that contained a common member. These observations suggest that different digestive enzymes can be secreted independently of each other.

7985 REGULATION OF AMYLASE RELEASE FROM DISPERSED PANCREATIC ACINAR CELLS. (Eng.) Gardner,

J. D.; Jackson, M. J. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *J. Physiol. (Lond.)* 270(2):439-454; 1977.

Factors influencing the release of amylase from dispersed pancreatic acinar cells were studied in the guinea pig pancreas. In the basal, unstimulated condition, cells released 2-3% of the total amylase present in 30 min. The rate of amylase release was stimulated 50-70% by C-terminal octapeptide of cholecystokinin (CCK-OP, maximally effective concentration, 3 x 10^{-10} M), carbamylcholine (maximally effective concentration, 10^{-5} M), secretin (maximally effective concentration $>10^{-6}$ M), vasoactive intestinal peptide (VIP, maximally effective concentration, 10^{-8} M), and cyclic AMP and guanosine 3',5' monophosphate (cyclic GMP), as well as their dibutyryl derivatives (maximally effective concentrations, 10^{-3} M). The responses to CCK-OP or carbamylcholine were potentiated by secretin, VIP, or dibutyryl cyclic AMP. The responses to secretin or VIP were potentiated by CCK-OP, carbamylcholine, or dibutyryl cyclic GMP. There appear to be two pathways for the regulation of amylase release from pancreatic acinar cells. One pathway can be stimulated by cholecystokinin or cholinergic agonists, and the response to these stimuli is mediated by cyclic GMP; the other pathway can be stimulated by secretin or VIP, and the response to these stimuli is mediated by cyclic AMP.

7986 LACK OF ADAPTATION OF PANCREATIC COLIPASE IN RATS AND MICE. (Eng.) Vandermeers-Piret, M. C.; Vandermeers, A.; Wijns, W.; Rathe, J.; Christophe, J. (Free Univ. Brussels Medical Sch., 1000 Brussels, Belgium). *Am. J. Physiol.* 232(2): E131-E135; 1977.

To study the regulation of pancreatic colipase in lipid and carbohydrate metabolism, a new automated potentiometric method for the determination of colipase was developed. The method takes advantage of the reactivation of purified lipase in the presence of bile salt and at pH 6.5. High-fat and high-starch diets induced an opposite regulation of lipase and amylase in the rat pancreas. The level of colipase, however, was not influenced by nutrition. During fasting and in alloxan diabetes, the specific activity of lipase almost doubled, that of amylase decreased sharply (from 234 ± 15 to 101 ± 5 pmol/mg protein during fasting; to 80 ± 9 pmol/mg protein in alloxan diabetes), and colipase was not affected in the rat pancreas. In obese hyperglycemic mice with hyperinsulinism and moderate diabetes, there was also no regulation of pancreatic colipase. Thus, at variance with a number of hydrolases, there was no dietary or hormonal adaptation of colipase. However, this was probably without any bearing on intraluminal lipolysis. In fact, comparison of lipase and colipase activities in the pancreas and small intestine suggests that colipase concentration is not a limiting factor of intraluminal lipolysis.

7987 AMINO ACID TRANSPORT IN THE RAT EXOCRINE PANCREAS. I. TRANSPORT OF NEUTRAL AMINO ACIDS AND THEIR UTILIZATION IN PROTEIN SYNTHESIS. (Eng.) Bieger, W.; Peter, S.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Heidelberg, W. Germany). *Cell Tissue Res.* 180(1):31-44; 1977.

In an effort to determine the significance of extracellular and intracellular amino acid pools for incorporation into proteins, the transport and utilization of three neutral amino acids in protein synthesis was studied in the rat, using isolated pancreatic lobules incubated *in vitro*. The extracellular and intracellular amino acid pools in this process were analyzed by removing the extracellular pool (labeled with inulin) by a cold-wash procedure. This procedure was especially useful in short-term experiments. Double-labeling experiments indicated a predominant utilization of the intracellular amino acid pool during protein synthesis. The advantage of studying isolated pancreatic lobule preparations compared to tissue fragments or slices was emphasized by fine structural analysis. Using freeze-etching techniques on the same preparations, differences described earlier in the distribution of membrane particles between luminal and lateral plasma membranes were confirmed, as was the occurrence of abundant gap junctions on both membrane faces.

7992 AN IMPROVED METHOD FOR THE ISOLATION OF HEPATOCYTES FROM LIVER SLICES: SELECTIVE REMOVAL OF TRYPAN BLUE-DYEABLE CELLS.

(Eng.) Bellemann, P.; Gebhardt, R.; Mecke, D. (Physiologisch-chemisches Institut der Universitat, Hoppe-Seyler-Strasse 1, D-7400 Tubingen, W. Germany). *Anal. Biochem.* 81(2):408-415; 1977.

An improved nonperfusion method for the isolation of hepatic parenchymal cells using a modified technique of collagenase/hyaluronidase digestion with liver slices is described. The yield of viable cells was considerably increased (30 x 10^6 cells/g liver) by bubbling all solutions with carbogen (95% O_2 and 5% CO_2) and by adding 100 mg% of glucose to all buffers used. Trypan blue-dyeable cells were selectively removed by a short trypsin-deoxyribonuclease incubation following the isolation procedure yielding a conspicuously high (>96%) viability index. The hepatocytes were ultrastructurally normal, and the cell suspension preserved their hormone sensitivity, as confirmed by insulin stimulation of the oxidative glucose metabolism. This simple method for isolating large numbers of viable cells may potentially be important for use with small liver pieces, such as biopsy samples, and it is suitable for maintaining hepatocytes in primary monolayer cultures to study enzyme regulation at the cellular level *in vitro*.

7993 A NOVEL PHYSIOLOGICAL ROLE OF LIVER GLUTATHIONE AS A RESERVOIR OF L-CYSTEINE.

(Eng.) Higashi, T.; Tateishi, N.; Naruse, A.; Sakamoto, Y. (Osaka Univ. Medical Sch., Fukushima-ku, Osaka 553, Japan). *J. Biochem. (Tokyo)* 82(1):117-124; 1977.

To verify the presence of more than one pool of glutathione in the liver, rats were fed a diet containing L-[^{35}S]cysteine. After chasing and exhaustion of the ^{35}S-label, a second diet containing L-[3,3-^{3}H]cystine was given. Subsequent starvation of the rats revealed differential decay of the ^{35}S and the ^{3}H incorporated into liver glutathione; the ^{3}H (incorporated later) disappeared rapidly on starvation, while a large portion of the ^{35}S (incorporated earlier) remained in the glutathione and did not disappear. A concomitant increase of ^{3}H-label in hepatic proteins during starvation indicated that cysteine derived from glutathione was probably incorporated into proteins. Analysis of the decay curve of the ^{35}S-labeled cysteine moiety of liver glutathione under normal feeding conditions revealed at least two types of glutathione with different apparent biological half-lives of 1.7 and 28.5 hr. Precipitous decay of ^{35}S-glutathione in the initial phase of starvation was accompanied by a rise in incorporation of ^{35}S into proteins. To prove the existence of the mobilization of the cysteine moiety of liver glutathione, rats were fed a gelatin-diet containing ^{35}S-cysteine followed by a tryptophan-fortified diet. Ingestion of the tryptophan diet induced a decrease in accumulated glutathione and increase of ^{35}S-label in hepatic and serum proteins, especially in serum albumin. There appear to be at least two pools of glutathione, one of which is labile and the other stable in a metabolic sense. The cysteine moiety of the labile liver glutathione is mobilized for protein synthesis when the amount of cysteine becomes rate-limiting. Otherwise, cysteine continues to be stored in liver glutathione. The stable pool of glutathione must serve for many reactions requiring sulfhydryl compounds in the liver.

7994 THE ROLE OF IRON IN THE REGULATION OF HEPATIC TRANSFERRIN SYNTHESIS.

(Eng.) Morton, A. G.; Tavill, A. S. (Dept. Biochemistry, Univ. Edinburgh Medical Sch., Teviot Place, Edinburgh EH8 9AG, Scotland). *Br. J. Haematol.* 36(3): 383-394; 1977.

The role of iron supply in the regulation of hepatic transferrin synthesis by the isolated perfused livers from male Sprague-Dawley rats was studied using nutritional iron deficiency as the experimental model. Nutritional iron deficiency (ID) caused a severe anemia when experimental and control animals were compared (hemoglobin, 5.0 ± 0.3 and 15.7 ± 0.4 g/dl for ID and control rats, resp.) and was associated with low plasma iron (8 ± 1 versus 41 ± 3 μM, $p<0.001$), raised plasma total iron-binding capacity (TIBC, 182 ± 7 versus 122 ± 7 μM, $p<0.001$), and reduced hepatic ferritin iron concentration (4.4 ± 0.5 versus 1.8 ± 0.2 μmol/10 g liver weight, $p<0.001$). The elevated plasma TIBC was accompanied by a significant increase in the transferrin release rate of ID animals as compared to controls (1.99 ± 0.26 versus 0.83 ± 0.06 mg/hr/10 g liver weight, $p<0.01$), whereas there was no significant change in the albumin release rate. The increased transferrin release was equated with enhanced *de novo* synthesis as evidenced by the inhibitory effect of cycloheximide (rate of transferrin release reduced to 25%) and by measurements of intrahepatic protein pools before and after perfusion that indicated a linear appearance of protein during the course of perfusion. Refeeding with iron (250 mg/kg diet for 24-48 hr before sacrifice) restored hepatic ferritin iron to the control level and increased total plasma iron beyond the control level ($p<0.01$-0.02) but did not significantly change the hemoglobin level or the transferrin release rate, although the latter was reduced towards normal. Transfusional correction (5-6 ml of a 0.5 packed cell volume of rat red cells given twice) of the anemia did not correct the plasma iron, plasma TIBC, or hepatic ferritin iron levels as compared with controls, nor was the transferrin release rate normalized (1.93 ± 0.21 and 0.71 ± 0.05 mg/hr/10 g liver weight, $p<0.001$). Phenobarbitone treatment (1 g/l in drinking water for 21 days before sacrifice and simultaneous with the respective diets) produced a marked fall in total hepatic iron concentration (4.5 ± 0.4 versus 11.8 ± 1.5 μmol/10 g liver weight for 10 and control animals, resp.,

$p<0.02$) but no improvement in hemoglobin, total plasma iron, or plasma TIBC concentrations, and it promoted a specific enhancement of transferrin release in both control and iron deficient livers. The concentration of liver iron stores appears to be a major regulatory factor in the control of hepatic transferrin synthesis.

7995 EFFECT OF A PITUITARY PEPTIDE ON LIVER TISSUE RESPIRATION. (Eng.) Landaburu, R. H.; De Lamo, R. (Wayne State Univ., Sch. Medicine, Detroit, MI 48201). *Proc. Soc. Exp. Biol. Med.* 155(3):377-381; 1977.

The capacity of a pituitary peptide to stimulate the liver was investigated in tissue respiration studies. Peptide concentrates stimulated oxygen uptake of rat liver slices by 20-40%. The stimulating effect appeared to be specific for the liver. The response of liver tissue was used to study the releasing mechanism of the peptide from the hypophysis. Cortisol (5×10^{-6} M) increased liver slice oxygen uptake only when pituitary tissue was included in the mixture. Epinephrine (2×10^{-7} M) produced the same results only when pituitary and hypothalamus tissue were included. The results support the conclusion that the pituitary peptide is a specific distinct substance that can be released from the hypophysis by cortisol or as a consequence of hypothalamus stimulation by epinephrine.

7996 STUDIES ON THE EFFECTS OF E. coli ENDOTOXIN ON CANALICULAR BILE FORMATION IN THE ISOLATED PERFUSED RAT LIVER. (Eng.) Utili, R.; Abernathy, C. O.; Zimmerman, H. J. (First Medical Sch., Naples, Italy). *J. Lab. Clin. Med.* 89(3):471-482; 1977.

This study was designed to determine the basic mechanisms underlying endotoxin-mediated cholestasis. The isolated liver from male CD rats was perfused without added taurocholate. After 30 min of perfusion, *E. coli* endotoxin (1 or 2 mg/100 ml) was added to the perfusate followed 15 min later by a 20-mg bolus of BSP. Bile and perfusate samples were taken over the next 45 min, and BSP clearance in the bile salt-independent bile flow (BSIF) was assessed. At 1 mg/100 ml, endotoxin decreased BSP excretion, expressed as total BSP, by 38% and increased the half-life of BSP in the recirculating perfusate by 26%. At 2 mg/100 ml, endotoxin caused a rapid decrease in biliary output as well as a slight decrease in bile salt excretion. Since the bile salt concentration in the bile increased simultaneously, it was concluded that the decreased bile flow was mainly due to a reduction in BSIF.

7997 SERUM BILE ACID ANALYSIS: A RAPID, DIRECT ENZYMATIC METHOD USING DUAL-BEAM SPECTROPHOTOFLUORIMETRY. (Eng.) Siskos, P. A.; Cahill, P. T.; Javitt, N. B. (New York Hosp.-Cornell Medical Center, New York, NY). *J. Lipid Res.* 18(5): 666-671; 1977.

The direct quantitative measurement of total bile acids in serum was achieved using an enzymatic fluorescent method with a dual-beam spectrophotofluorimeter. Using a 3α-hydroxysteroid dehydrogenase, oxidation of bile acids with NAD is completed in 200 sec, the observed NADH fluorescence being proportional to the concentration of serum bile acids. This method is rapid (8 min/individual sample), has an intrinsic sensitivity of ± 1 μM of total bile acids, and requires no sample preparation and less than 0.8 ml of serum. Paired data analysis using enzymatic fluorescence and gas-liquid chromatographic methods gives a correlation coefficient of 0.99 for 34 samples over the range 2-530 μM.

7998 EFFECT OF TYPE AND AMOUNT OF DIETARY FAT AND 1,2-DIMETHYLHYDRAZINE ON BILIARY BILE ACIDS, FECAL BILE ACIDS, AND NEUTRAL STEROLS IN RATS. (Eng.) Reddy, B. S.; Mangat, S.; Sheinfil, A.; Weisburger, J. H.; Wynder, E. L. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595). *Cancer Res.* 37(7):2132-2137; 1977.

The effect of the source (corn oil or lard) and the quantity (5% or 20%) of dietary fat in combination with 1,2-dimethylhydrazine (DMH) administration on the composition of biliary bile acids, fecal bile acids, and neutral sterols was studied in rats exposed to a given dietary regimen for two generations prior to s.c. treatment with DMH (10 mg/kg body weight once a week for 20 weeks). Biliary excretion of total bile acids as well as cholic acid, β-muricholic acid, ursodeoxycholic acid, and deoxycholic acid was higher in rats fed a diet containing 20% corn oil or lard than it was in rats fed diets containing 5% corn oil or lard ($p<0.05$). Treatment of animals with DMH produced an increase in biliary total bile acids, cholic acid, hyodeoxycholic acid, and deoxycholic acid irrespective of diets ($p<0.05$). High-fat (corn oil or lard at 20% level) intake was associated with an increased excretion of fecal neutral sterols and bile acids. The excretion of deoxycholic acid, lithocholic acid, and 12-ketolithocholic acid was increased in rats fed high-fat diets. The source of fat had no major influence on the excretory pattern of cholesterol metabolites and bile acids. DMH-treated animals excreted higher levels of fecal coprostanol, coprostanone, deoxycholic acid, lithocholic acid, and 12-ketolithocholic acid than did controls. The results suggest that high dietary fat levels increase the hepatic synthesis and/or metabolism of cholic acid, β-muricholic acid, ursodeoxycholic acid, and deoxycholic acid and thereby increase the biliary levels of these bile acids.

7999 HEPATIC ENZYMES, THEIR INDUCTION AND USEFULNESS IN PREDICTING MAXIMAL SERUM BILIRUBIN LEVELS IN PREMATURE NEWBORN INFANTS. (Eng.) Bartels, H.; Fenner, A.; van der Merwe, W.; Barbalatt, S.; Wolfsdorf, J. (Dept. Pediatrics, Univ. Kiel, Frobelstrasse 15, D-2300 Kiel, W. Germany). *Eur. J. Pediatr.* 125(2):97-102; 1977.

The effectiveness of phenobarbitone and nikethamide in lowering the serum bilirubin level(s) (SBL) in neonatal hyperbilirubinemia of nonhemolytic origin was investigated along with the usefulness of serum hepatic enzyme activity measurements in predicting maximum SBL. Twenty-two infants were given nikethamide (100 mg/kg/day, p.o., 6 divided doses) from the age of 6 hr for 4 days and phenobarbitone (10 mg/kg/day, p.o., 2 divided doses) for 3 days. Twenty-two infants were not treated, and they served as controls. During the first week of life, mean maximum SBL in control infants were achieved by day 5, but the levels in the treated group showed a constant decline from day 3 onward. The mean SBL for the two groups were significantly different from day 3 onward. In controls, nine total SBL were between 12 and 18 mg%, but only one such level (12.7 mg%) was recorded in the treated group. From day 4 onward, the difference between the means was ≥ 4 mg%. A significant correlation ($p<0.05$) was found between the day 1 serum γ-glutamyl transferase (SGGT) level and the mean SBL. A significant correlation was also found between birth weight and mean SBL ($p<0.05$). When the ratio of the log of SGGT activity (day 1) to birth weight was calculated, the significance of the correlation with mean SBL increased ($p<0.01$). No infant with a log SGGT/birth weight ratio of <0.9 on the first day of life achieved an SBL of >12 mg%, but all but two infants with ratios >1.1 on day 1 eventually reached mean SBL >12 mg%.

8000 HEPATIC SECRETION AND TURNOVER OF SERUM PHOSPHATIDYLCHOLINE-CHOLESTEROL ACYLTRANSFERASE IN MALE AND FEMALE RATS.

(Eng.) Soler-Argilaga, C.; Russell, R. L.; Goh, E. H.; Heimberg, M. (Univ. Missouri, Sch. Medicine, Columbia, MO 65201). *Biochim. Biophys. Acta* 488(1):69-75; 1977.
